PREFACE

THE present work is based on lectures which the author is accustomed to give at Yale University on advanced calculus and the theory of functions of real variables. It falls in two volumes, and the following remarks apply only to the first.

The student of mathematics, on entering the graduate school of American universities, often has no inconsiderable knowledge of the methods and processes of the calculus. He knows how to differentiate and integrate complicated expressions, to evaluate indeterminate forms, to find maxima and minima, to differentiate a definite integral with respect to a parameter, etc. But no emphasis has been placed on the conditions under which these processes are valid. Great is his surprise to learn that they do not always lead to correct results. Numerous simple examples, however, readily convince him that such is nevertheless the case.

The problem therefore arises to examine more carefully the conditions under which the theorems and processes of the calculus are correct, and to extend as far as possible or useful the limits of their applicability.

In doing this it soon becomes manifest that the style of reasoning which the student has heretofore employed must be abandoned. Examples of curves without tangents, of curves completely filling areas, and other strange configurations so familiar to the analyst of to-day, make it clear that the rough and ready reasoning which rests on geometric intuition must give way to a finer and more delicate analysis. It is necessary for him to learn to think in the ϵ , δ forms of Oauchy and Weierstrass.

We have here the beginnings of the theory of functions of real variables, and the twofold problem just sketched characterizes sufficiently well the subject-matter and form of treatment of the present volume. To obvin a foundation, the author has beginn by developing the real number system after the manner of Cantor and Deckening, bottlating the theory of positive untegers. To obtain sufficient generality, he has employed from the start the more simple properties of point aggregates. So attempt however, has been made to state every theorem with all possible generality. The author has allowed himself a wide liberty in this respect. Some theorems are stated under very broad conditions, while others are enunciated under extremely narrow ones. Some of these latter will be taken unlater on

Two features of this volume may be mentioned here. In the first place, the Euchdean form of exposition has been adopted Each theorem with its appropriate conditione is stated and then proved. Without doubt this makes the book less attractive to read, but on the other hand it incresses its usefulness as a hook of reference. One is thus often saved the labor of running through a complicated piece of reasoning to pick up emilty conditions which have been introduced, sometimes without any explicit mention, in the course of the demonstration.

Secondly, numerous examples of incorrect forms of reasoning currently found in standard works on the calculus have been scattered through the earlier pirt of the volume. It is the authors experience that nothing simulates the students critical sense so powerfully as to ask him to detect the flans in a piece of reasoning which at an earlier stage of his truining he considered correct.

A few new terms and symbols have been introduced, but only after long deliberation. It is boyed that their employment sufficiently familiates the reasoning and the enmeation of certain theorems, to justify their introduction. It may be well to note here the author's use of the word 'any in the sense of any one at pleasure, and not in the sense of some one. The words' each, "every," "some," "any," are often used in an indiscriminate manner and to this is due a purt of the difficulty the beginner experiences in undertrapproximally as

No attempt has been made to attribute the various results here given to their respective authors. That has been rendered unnecessary by the very full bibliographies of the Encyclopadie do: PREFACE v

Mathematischen Wissenschaften. The author feels it his pleasant duty, however, to acknowledge his large indebtedness to the writings of Jordan, Stolz, and Vallée-Poussin. He hopes, however, that it will be found that he has not used them servilely, but in an individual and independent manner.

Finally, he wishes to express his hearty thanks to his friend Professor M. B. Porter, and to his former pupil Dr. E. L. Dodd, for the unflagging interest they have shown during the composition of this volume and for their many and valuable suggestions.

JAMES PIERPONT.

New Haven, Conn., August, 1905.

NOTE

A list of some of the mathematical terms and symbols employed in this work will be found at the end of the volume.

FUNCTION THEORY OF REAL VARIABLES

CHAPTER I

RATIONAL NUMBERS

Historical Introduction

1. The reader is familiar with the classification of real numbers into rational and irrational numbers. The rational numbers are subdivided into integers and fractions.

Besides the real numbers there is another class of numbers currently employed in modern analysis, viz. complex or imaginary numbers. In this work we shall deal almost exclusively with real numbers.

Historically, the first numbers to be considered were the positive integers 1, 2, 3, 4, 5, 6, . . . (3)

We shall denote this system of numbers by 3.

It is not our intention to develop the theory of these numbers; instead, we shall merely call attention to some of their fundamental properties.*

In the first place, we observe that the elements of \Im are arranged in a certain fixed order; that is, if a, b are two different numbers, then one of them, say a, precedes the other b. This we express by saying that a is less than b, or that b is greater than a. In symbols a < b, b > a.

* For an extended treatment of this subject we refer to the excellent work of O Stolz and J. A. Gmeiner, Theoretische Arithmetik, Leipzig, 1900.

We say the system 3 is ordered. Furthermore, if a=b, b=a, then a=c. Also if a=b and b>c, then a>c. Also if a>b, b>c then a>c. Also if a>b, b>c then a>c. Secondly, we observe that the system 3 is infinite, after each element a follows another element, and so on without end

On the elements of 3 we perform four operations, viz addition, subtraction, multiplication, and division. They are called the four retional operations. Of these operations, two may be garded as direct, viz addition and multiplication. The other two are their inverses, viz subtraction the inverse of addition, and division, the inverse of multiplication.

The formal laws governing addition are the associative law, expressed by the formula

$$a+(b+e)=(a+b)+e$$

and the commutative law, expressed by

$$a + \delta = \delta + a$$

As regards the position of a + b in the system \Im , relative to a or b, we have

We have also the relation

$$a+\delta>a'+\delta$$
, if $a>a'$

The formal laws governing multiplication are the three following

The associative law, expressed by

The distributive law, expressed by

$$(a+b)c=ac+bc$$
 $a(b+c)=ab+ac$

The commutative law, expressed by

$$ab = ba$$

We have also the relation, with respect to order,

Another important property is this:

If
$$ac = bc$$
, then $a = b$.

The result of subtracting b from a is defined to be the number x in \mathfrak{F}_{a} , satisfying the relation

$$a = b + x$$
.

But when $a \ge b$, no such number exists in \Im .

Similarly, the result of dividing a by b is defined to be the number x in \Im , satisfying the relation

$$a = bx$$
.

If, however, a is not a multiple of b, no such number exists in \Im . Thus when we limit ourselves to the number system \Im , the two operations of subtraction and division cannot always be performed. In order that they may be, we enlarge our number

formed. In order that they may be, we enlarge our number system by introducing new elements, viz. fractions and negative numbers.

The introduction of fractions into arithmetic was comparatively easy; on the contrary, the negative numbers caused a great deal of trouble. For a time negative numbers were called absurd or fictitious. That the product of two of these fictitious numbers, -a and -b, could give a real number, +ab, was long a stumbling block for many good minds.

The introduction of irrational numbers, i.e. numbers like

$$\sqrt{2}$$
, $\sqrt[3]{5}$, $\pi = 3.14159 \dots$, $e = 2.7182 \dots$

never excited much comment. In actual calculations one used approximate rational values, and it was perfectly natural to subject them to the same laws as rational numbers. It is true that the Greeks of the time of Euclid were perfectly aware of the difficulties which beset a rigorous theory of incommensurable magnitudes; witness the fifth and tenth book of Euclid's Elements. But these subtle speculations found little attention during the Renaissance of mathematics in the seventeenth and eighteenth centuries. The contemporaries and successors of Newton and Leibnitz were too much absorbed in developing and applying the infinitesimal calculus to think much about its foundations.

At the close of the eighteenth and the beginning of the nine teenth centuries a change of attitude is observed. Gauss, La genuge, Cauchy, and Abel called for a return to the rigor of the ancient Greek geometers. Certain paradoxes and even results obvously false had been obtained by methods in good repute. It became evident that the foundations of the calculus required a critical revision.

Abel in a letter to Hansteen in 1826 writes "I mean to devote all my strength to spread light in the immense obscurity which prevails to day in analysis. It is so devoid of all plan and system that one may well be astonished that so many occupy themselves with it, — what is worse, it is absolutely devoid of rigor. In the higher analysis there exist very few propositions which have been demonstrated with complete rigor. Everywhere one observes the unfortunate habit of generalizing without demonstration, from special cases, it is indeed narvelous that such matched lead so rarely to so called paradocas."

In another place he writes † 'I believe you could show me but few theorems in infinite series to whose demonstration I could not urge well founded objections. The binomial theorem itself has never been rigorously demonstrated. Taylors expansion, the foundation of the whole calculus, has not fared better.

The critical movement inaugurated by the shove-mentioned mathematicans found uts greatest exponent in Weierstrass. It is no doubt largely due to his teachings that we may bosst to day that the great structure of modern sandysss is built on the secured foundations known, that its methods have attained, if not sur passed, the justly famed rigor of the ancient Greek geometers. The saying of D Alembert, "Aller en avant, is for yous vinedra," has lost its force. To day, it is not faith that is required, but a little patience and maturity of mand.

As Wecestrass has shown, it is necessary, in order to place analysis on a satisfactory basis, to go to the very root of the matter and create a theory of irrational numbers with the same care and rigor as contemplated by Euclid, in his theory of incommensurable magnitudes, only on a fire grander scale it is to

⁴ Abel, Eugres 2- ed , Val. 2 p 253.

early to make the reader see the necessity of this step, but it will appear over and over again in the course of this work.

Fractions

2. Before taking up the theory of irrational numbers, we wish to develop in some detail the modern theory of fractions and negative numbers. We shall rest our treatment of these numbers on the properties of the positive integers 3, which we therefore suppose given. One of these properties, on account of its importance, deserves especial mention, viz.:

If the product ab is divisible by c, and if a and c are relatively prime, then b is divisible by c.

3. Let us begin with the positive fractions. As we saw, division of a by b, where a, b are two numbers in \Im , is not possible unless a is a multiple of b. Our object is therefore to form a new system of numbers, call it \Im , formed of the numbers of \Im and certain other numbers, in which division shall be always possible.

We start by forming all possible pairs of numbers in 3. These pairs we represent by the notation

$$\alpha = (a, a'), \beta = (b, b') \cdots$$

In any one of these pairs, as $\alpha = (a, a')$, we call a the first constituent and a' the second constituent of α .

The system \mathfrak{F} consists of the totality of these pairs α , β , ...

The elements of \mathfrak{F} we have represented by the symbol (a, a'). Any other symbol would do. The customary ones are a/b and a:b.

We have purposely avoided these symbols, so familiar to the reader, in order that his attention shall be more closely fixed on the logical processes employed.

4. The objects of \mathfrak{F} have as yet no properties; we proceed to assign them one arithmetic property after another, taking care that no property shall contradict preceding ones. We begin by setting \mathfrak{F} in relation to \mathfrak{F} . We say: (a,a') shall be a number c, in \mathfrak{F} , when a=a'c. Thus, any element of \mathfrak{F} whose first constituent is a multiple of its second, is an element of \mathfrak{F} , i.e. a positive integer.

From this follows that every number a of 3 hes in 3 For, (a, 1) hes in 3 On the other hand

Hence a hes in F-

$$(a, 1) = a$$

5. We define next the terms, equal, greater than, less than

Let
$$a = (a, a'), \beta = (b, b')$$

We say a \(\beta \) according as ab' \(\beta \) d'b

We observe that to decide the equality or inequality of two elements in §, the operations required are on the elements of §

6 We deduce now some of the consequences of the above defination of equality and inequality In the first place, suppose α, β both he in \mathfrak{F} , $i \in let$

$$a = (aa', a') = a, \beta = (bb', b') = b,$$

by 4. Now, according to the definition in 5, $\alpha \ge \beta$

according as

Thus, when a considered as a number of \Im , equals β considered as a number of \Im , the two are equal, considered as numbers in \Im , and conversely.

7 If

$$\alpha = \gamma$$
, $\beta = \gamma$, then $\alpha = \beta$

For, let

$$a = (a, a'), \beta = (b, b'), \gamma = (c, c').$$

Since $a = \gamma$, ac' = a'c, by 5. Since $\beta = \gamma$, bc' = b'c

$$\beta = \gamma$$
, $bc^i = b^i \sigma$ (2)

(1

Multiply 1) by 6', and 2) by a' and subtract.

$$ab'c' = a'bc'$$

$$ab' = a'b \quad \therefore a = A$$

Then by 5. 8. The two numbers (ma, ma') and (a, a') are equal.

This follows at once from the definition in 5. From this fact we conclude: We can multiply the first and second constituent of a number without changing its value.

Conversely:

If the first and second constituents of a number have a common factor, it can be removed without changing the value of the number.

9. Let a_i d' be relative prime. For $w=(a_i, a')$ and $\beta=(b, b')$ to be equal, it is necessary and sufficient that

$$b = ta, b' = ta'. (1$$

Obviously if 1) holds, $\alpha = \beta$. The condition 1) is thus sufficient. It is necessary. For, from $\alpha = \beta$, we have

$$ab^{i}=a^{i}b. \tag{2}$$

We apply now the property mentioned in 2. Since a'b is divisible by a, by virtue of 2); and since a, a' are relative: prime, b must be divisible by a. Say

$$b = ta.$$
 (3)

Similarly, since ab' is divisible by a', and a, a' are relative prime, b' must be divisible by a'. Say

$$b'' = sa'. (4$$

Putting 3), 4) in 2), we get s = t. Hence 3), 4) give now 1).

10. Our next step is to define the four rational operations on the elements of §.

We begin by defining the two direct operations.

Let
$$\alpha = (a, a'), \beta = (b, b').$$

We define addition by the equation,

$$\alpha + \beta = (ab' + a'b, a'b'); \tag{1}$$

and multiplication, by

$$\alpha\beta = (ab, a'b'). \tag{2}$$

It can be shown that the operations just defined enjoy the same properties as those of ordinary fractions. Without stopping to show this in detail, we demonstrate a few of these properties, by way of illustration

11 Let
$$a$$
, β lie in β , and say
$$a = (aa', a') = a, \beta = (bb', b') = b.$$

Then $\alpha + \beta$ as defined in 10, 1), should give $\alpha + b$, and $\alpha\beta$, as defined in 10, 2), should give ab

This is indeed so For

$$a + \beta = (aab' + abb, ab), \text{ by } 10, 1)$$

= $(a + b, 1), \text{ by } 8$
= $a + b, \text{ by } 4$

Similarly,

$$a \beta = (aabb, a'b), by 10, 2)$$

= $(ab, 1) by 8$
= $ab, by 4$

12 From ay = Sy, follows a = B

For, let ~= (c, o'), we have

$$ay = (a \ a)(c \ c) = (ac, a'c'), \text{ by } 10, 2)$$

$$By = (b \ b)(c, c) = (bc, bc')$$

Since by hypothesis $\alpha y = \beta y$, we have

by hypothesis $\alpha \gamma = \beta \gamma$, we have acb c' = acbc, by 5.

$$ab = ab$$

 $a = \beta$, by 5

13 We establish now the following relations:

1)
$$\alpha + \beta > \alpha$$

2) If
$$\beta > \gamma$$
 then $\alpha + \beta > \alpha + \gamma$.

3) I.
$$\alpha + \beta = \alpha + \gamma$$
, then $\beta = \gamma$

To prove 1):

$$\alpha + \beta = (a, a') + (b, b') = (ab' + a'b, a'b')$$
, by 10, 1).

But

$$a'(ab'+a'b)>aa'b'.$$

$$\therefore \alpha + \beta > \alpha$$
, by 5.

To prove 2):

$$\alpha + \beta = (ab' + a'b, a'b')$$

= $(ab'c' + a'bc', a'b'c')$, by 8. (4)

Similarly,

$$\alpha + \gamma = (ac' + a'c, a'c')$$

$$= (ab'c' + a'b'c, a'b'c').$$
(5)

By hypothesis $\beta > \gamma$; hence, by 5,

$$bc' > b'c. (6$$

Comparing 4), 5), we see the second constituents are equal, while the first constituent in 4) is greater than the first constituent in 5), by virtue of 6). From this follows, by 5, that $\alpha+\beta>\alpha+\gamma$, which is 2).

To prove 3):

Suppose the contrary; then since $\beta \neq \gamma$, either $\beta > \gamma$ or $\beta < \gamma$. If $\beta > \gamma$, then $\alpha + \beta > \alpha + \gamma$, by 2).

If $\beta < \gamma$, then $\alpha + \gamma > \alpha + \beta$, by 2). (8)

But both 7), 8) contradict the hypothesis that $\alpha + \beta = \alpha + \gamma$.

To prove 4):

Since
$$a > \beta$$
, $ab' > a'b$. (9)

Since
$$\beta > \gamma$$
, $bc' > b'c$. (10)

From 9), 10) we have

$$abb'c' > a'bb'c$$
;

whence

$$ac' > a'c$$
.

Hence, by 5,

$$\alpha > \gamma$$
.

14 As an illustration of the demonstration for the formal laws governing addition and multiplication, let us show that the dis tributive law holds in & We wish to prove that

1)
$$a(\beta + \gamma) = a\beta + a\gamma$$
Now
$$\beta + \gamma = (bc' + b'c, b'c'), \text{ by } 10, 1),$$

$$a(\beta + \gamma) = (a, a') \text{ (bc' + b'c, b'c')}$$

$$a(bc' + ab'c, a'b'c'), \text{ by } 10, 2).$$

Also

$$a\beta = (ab, a'b'), a\gamma = (ac, a'c')$$

 $a\beta + a\gamma = (aa'bc' + aa'b'c, a'b'c')$

= (abe' + ab'c, a'b'c'), by 8 3) The comparison of 2), 3) gives 1)

15 We turn now to the inverse operations, subtraction and division, considering first division

We define the quotient of a by B to be the element or elements. E. if any exist, of it which satisfy the relation

$$\alpha = \beta \xi$$
 (1

Set $\xi = (x, x')$ Since ξ must satisfy 1), we have

$$(a, a') = (b, b')(x, x') = (bx, b'x')$$

The first and third members give, by 5.

$$ab'x' = a'bx,$$
 (2)

which x, x' must satisfy A solution of 2) is obviously

$$x = ab', \quad x' = a'b,$$

 $\dot{\xi} = (ab', a'b)$

is a solution of 1) This is the only solution of 1) For. sup pose 7 is a solution Then by definition

which gives, by 12,

Thus.

$$\beta_{i}^{t} = \beta_{\eta_{i}}$$

 $\dot{t} = \eta$

16. The quotient of α by β , we shall now represent by α/β . All the numbers of \mathfrak{F} may be regarded as quotients of numbers in \mathfrak{F} . For, let $\alpha = (a, a')$ be any number of \mathfrak{F} . It evidently satisfies the equation a = a'x,

which, as we have just seen, admits only one root, viz. the quotient of a by a'.

Hence
$$\alpha = (a, a') = a/a'$$
.

Thus the elements or numbers in F are ordinary positive fractions.

17. We have now this result. In the system \mathfrak{F} , division is always possible and unique. In the old system \mathfrak{F} , this is not true; the division of a by b being only possible when a is a multiple of b. We see, then, that, on properly enlarging our number system by introducing new elements, we obtain a system \mathfrak{F} which has this advantage over \mathfrak{F} , that the quotient of any two numbers in \mathfrak{F} exists and is unique.

18. We treat now subtraction.

We define the result of subtracting β from α to be the element or elements, call them ξ , in \Re , which satisfy the relation

$$\alpha = \beta + \xi. \tag{1}$$

If $\beta \ge \alpha$, there exists no number ξ in \Re which satisfies 1). For, if $\beta = \alpha$, $\beta + \xi = \alpha + \xi > \alpha$, by 13, 1).

If $\beta > \alpha$, $\beta + \xi > \alpha + \xi$, by 13, 2). Also $\alpha + \xi > \alpha$, by 13, 1).

 $\therefore \beta + \xi > \alpha, \text{ by } 13, 4).$

Thus when $\beta \equiv \alpha$, $\beta + \xi > \alpha$, and hence $\beta + \xi \neq \alpha$.

Suppose then, that $\beta < \alpha$. Then

$$ab' > a'b. (2$$

From 1), we have, setting $\xi = (x, x')$;

$$(a, a') = (b, b') + (x, x')$$

= $(bx' + b'x, b'x')$, by 10, 1).

Hence by 5, observing 2),

$$a'b'x = x'(ab' - a'b). \tag{3}$$

A solution of 3) is evidently

 $z = ab^{i} - a^{i}b, z^{i} = a^{i}b^{i}$

Hence

 $\xi = (ab' - a'b, a'b')$ is a solution of 1)

This is the only solution, for if n is a solution, we have, by

definition,
$$\alpha = \beta + \eta$$
 (4)

The comparison of 1), 4) gives

Hence, by 13, 3), $\beta + \xi = \beta + \eta.$ $\xi = \eta$

19 We have thus this result. In the system β, the subtraction of β from a is possible and unsyes, when a > β, when a < β, it is impossible. That is, there is no number ξ in β which satisfies 18, (1) When subtraction is possible, we represent the result of subtracting β from a by a - β.</p>

Negatue Numbers

20 In the system of posture fractions \hat{g}_1 authraction is only possible when the numeral is greater than the subtributed. To remove this restriction, we propose to form a new number system R_c which contains all the numbers of \hat{g}_1 and in which subtraction of a greater from a less shall be possible Since the method of forming R is identical with that employed for \hat{g}_1 , when the numbers in \hat{g}_2 we now denote by a_1 , b_1 , while the Greek Letters a_1 , \hat{g}_2 , p_3 , a shall denote numbers in the new system R.

21 1 We begin by taking the elements of \mathfrak{F} in pans, to form new objects, which we denote by the new symbol $\{a,b\}$ The totality of all such pairs forms the system R

Next, we place R in relation to \Re Let $a = \{a, b\}$ In case a > b, we say a shall be the number a - b, which obviously lies in

F. Thus every number in F lies in R. For, let a be any number in F, and let b be any other number in F. Then

$$\{a+b,b\}=(a+b)-b=a;$$

that is, a lies in R.

2. We next order the system R. We say

$$\{a, a'\} \geqslant \{b, b'\},\$$

according as

$$a+b' \geqslant a'+b. \tag{1}$$

3. Addition is defined by the relation

$$\alpha + \beta = \{a, a'\} + \{b, b'\} = \{a + b, a' + b'\}.$$
 (2)

Multiplication is defined by

$$\alpha \cdot \beta = \{ab + a'b', ab' + a'b\}. \tag{3}$$

4. As a consequence of 1), we have

$$\{a, a'\} = \{a + b, a' + b\},$$
 (4)

where b is any number in \mathfrak{F} .

In words, 4) states:

We can add the same number b to both constituents of $\alpha = \{a, a'\}$ without changing the value of α ; and if a, a' are both > b, we can subtract b from both constituents, without altering the value of α .

- 5. It is easy now to prove results analogous to those in 6, 7, 11, 14; in particular the associative, commutative, and distributive laws.
- 22. According to our definition of equality, all the elements of R whose first and second constituents are the same, *i.e.* all elements of the type

are equal. We set

$$\{a, a\},\$$

 $\{a, a\} = 0,$

and call this number zero.

Then, if in $\alpha = \{a, a'\}$,

$$a > a', \alpha > 0$$
;

if a' > a,

$$\alpha < 0$$
.

Numbers in K which are >0, are called positive; those <0, are called negative. The number 0 is mether positive nor negative. From this, it follows that the positive numbers of R are simply the numbers of \mathfrak{F} , while 0 and sill negative numbers do not lie in \mathfrak{F}

23 1. We observe that

 $\pi \theta = \theta = 0$ a.
To prove 1)

Then $a + \theta = \{a + b, a' + b\}$, by 21, 3,

= a. To prove 2)

$$a = \{ab + a \ b, ab + a'b\}$$

= 0, by 22

2. We also note the relations

$$0+0=0, \ 0 \ 0=0$$

24 We can prove now easily the Rule of signs. The product of two positive or two negative numbers is positive. The product of a positive and a negative number is negative.

Let a= {a, a'}, B= {b b'}.

1°. $\alpha, \beta > 0$, then $\alpha \beta > 0$

$$\alpha\beta = \{ab + a'b', ab' + a'b\} = \{b(\alpha - \alpha') + a'b', ab'\}, by 21, 4$$

= $\{b(\alpha - \alpha'), b'(\alpha - \alpha')\}, by 21, 4$

$$>0$$
, since $b(a-a')>b'(a-a')$

2° $\alpha, \beta < 0$, then $\alpha\beta > 0$.

Here a'>a, b'>b, by 22.

..
$$\alpha\beta = \{ab + a'(b' - b), ab'\}$$
, by 21, 4;
 $= \{a'(b' - b), a(b' - b)\}$, by 21, 4;
 > 0 , since $a'(b' - b) > a(b' - b)$.
 $\alpha > 0$, $\beta < 0$, then $\alpha\beta < 0$.
 $\alpha > a'$, $b' > b$.
.. $\alpha\beta = \{ab + a'(b' - b), ab'\}$

 $\begin{array}{l}
\Rightarrow \alpha\beta = \{ab + a'(b' - b), ab'\} \\
= \{a'(b' - b), a(b' - b)\} \\
< 0, \text{ since } a'(b' - b) < a(b' - b).
\end{array}$

25. The product of any two numbers in R vanishes when, and only when, one of the factors is zero.

Let α , β be any two numbers in R.

We saw in 23 that

go.

Here

$$\alpha\beta=0$$
,

when either α or $\beta = 0$.

Conversely, if $\alpha\beta = 0$, either α or $\beta = 0$.

For, if neither α nor $\beta = 0$, these numbers are either positive or negative. Their product is therefore either positive or negative by 24, and hence not zero. This is a contradiction.

26. Let us consider the following important formulæ, viz.:

1) If
$$\beta > \gamma$$
, then $\alpha + \beta > \alpha + \gamma$.

2) From
$$\alpha + \beta = \alpha + \gamma$$
, follows $\beta = \gamma$.

3) If
$$\alpha \neq 0$$
 and $\alpha \beta = \alpha \gamma$, then $\beta = \gamma$.

To prove 1):

$$\alpha + \beta = \{a + b, a' + b'\}, \text{ by 21, 3;}$$

$$= \{a + b + c', a' + b' + c'\}, \text{ by 21, 4.}$$
(4)

Similarly,

$$\alpha + \gamma = \{a + c, a' + c'\} = \{a + b' + c, a' + b' + c'\}.$$
 (5)

Since $\beta > \gamma$,

$$b+c' > b'+c$$
, by 21, 2.

$$\therefore a+b+c'>a+b'+c. \tag{6}$$

If we now apply the definition for greater than given in 21, 2 to $\alpha + \beta$ and $\alpha + \gamma$, the relations 1), 5), 6) show that $\alpha + \beta > \alpha + \gamma$

Suppose the contrary, i.e. suppose $\beta > \gamma$ or $\beta < \gamma$

If
$$\beta > \gamma$$
, $\alpha + \beta > \alpha + \gamma$, by 1)

If
$$\gamma > \beta$$
, $\alpha + \gamma > \alpha + \beta$ by 1)

Thus in both cases, $\alpha + \beta \neq \alpha + \gamma$, which is contrary to hypothesis. Hence $\beta = \gamma$

To proce 3)

From $\alpha\beta = \alpha\gamma$ we have $\alpha(\beta - \gamma) = 0$

Applying 25, we have
$$\beta = \gamma$$

27 We turn now to subtraction. This we define as in \mathfrak{F} , viz the result of subtracting β from α is the element or elements ξ , of R, which satisfy $\alpha = \beta + \xi$

This equation gives, setting $\xi = \{x, x'\}$,

$$\{a, a'\} = \{b, b'\} + \{x, x\} = \{b + x, b + x'\}, \text{ by 21, 3}$$

Hence by 21, 2,

$$a+b'+x'=a+b+x$$

This equation is evidently satisfied by

$$x=a+b', x'=a'+b$$

is a solution of 1)
$$\xi = \{a+b', a'+b\}$$
 (2)

Thus is the only solution For, let η be a solution Then by definition, $\alpha = \beta + \eta$ (3)

The comparison of 1), 3) gives

$$\beta + \xi = \beta + \eta$$

Hence by 26, 2),

28. We have thus this result: in the system R subtraction is always possible and unique. The result of subtracting β from α , we represent by $\alpha - \beta$; it is a number in R. Then any number $\alpha = \{a, a'\}$ in R, is the result of subtracting a' from a, or

For,
$$a = a - a'$$
.
Similarly, $a = \{a + b, b\}$, by 21, 4.
Hence $a' = \{a' + b, b\}$.
 $a' = \{a' + b, b\}$.
 $a - a' = \{a + b, b\} - \{a' + b, b\}$
 $= \{a + 2b, a' + 2b\}$, by 27, 2)
 $= \{a, a'\}$, by 21, 4.

29. 1. Let $\alpha = \{a, a'\}$ be any number of R. The number $\{a', a\}$ is called *minus* α , and we write

Then
$$\{a', a\} = -\alpha.$$

$$-(-\alpha) = -\{a', a\} = \{a, a'\} = \alpha.$$

$$\alpha + (-\alpha) = \{a, a'\} + \{a', a\}$$

$$= \{a + a', a + a'\} = 0$$

$$= \alpha - \alpha.$$

If α is positive, $-\alpha$ is negative; and conversely, if α is negative, $-\alpha$ is positive.

2. The number $-\alpha$ may be defined as the number ξ , such that $\alpha + \xi = 0$.

For, $\xi = -\alpha$ satisfies this equation; and, as we saw in 27, this equation admits but one solution. This shows that the numbers in $R, \neq 0$, may be grouped in pairs, such that their sum is zero.

3. If $-\alpha = -\beta$, then $\alpha = \beta$. For, multiplying both sides of $-\alpha = -\beta$ by -1, we get $\alpha = \beta$.

4. Every number α , of R, different from zero, can be written in the form $\alpha = a$, or $\alpha = -a$,

where a is a number in \mathfrak{F} .

For if $\alpha > 0$, we already know by 22 that α is a number in §. If a < 0, then -a is positive, so that -a = a, a number in § Multiplying this equation by -1, we get

30 1. We treat now division.

We say: the result of dividing a by B is the number or num-

bers 5 of R, such that a = FB.

Suppose $\beta \neq 0$; then there is one and only one number E; i.e. in this case, division is possible and unique, There can be at most one. For, if η satisfies 1), we should have

a = n8

Comparing 1), 2), we have

 $\xi \beta = \eta \beta$; whence by 26, 3), F = n.

To show that there is always one solution of 1), we have the following cases.

Let $\alpha, \beta > 0$; then $\alpha = a, \beta = b$, by 29, 4; and 1) becomes $a = \xi b$.

But by 15 the solution of 3) is

F = (a, b) = a/b.

Let a, B<0; theu $\alpha = -a$, $\beta = -b$, by 29, 4. Then 1) becomes

 $-a=-\delta F$:

or by 29, 3, a = bF

Hence as before. $\xi = a/b$.

Let a>0, $\beta<0$; then a=a, $\beta=-\delta$, and 1) becomes

a = -b E

14

1

(2

(3

Set $-\xi = \eta$; then 4) gives

$$a = b\eta$$
.

Hence,

$$\eta = a/b$$

 $\xi = -a/b$.

If a < 0, and $\beta > 0$, we get again

$$\xi = -a/b$$
.

Finally, let $\alpha = 0$; then 1) becomes

 $0 = \beta \xi$.

Hence by 25,

 $\xi = 0$.

2. We consider now the case that $\beta = 0$.

The equation 1) admits now no solution, unless $\alpha = 0$ also. For, when $\beta = 0$, $\beta \xi = 0$, whatever ξ may be.

If now $\alpha = 0$, the equation 1) is satisfied for every number ξ in R. We have thus this result: When the divisor is zero, division is either impossible or entirely indeterminate.

For this reason, division by zero is excluded in modern mathematics. The admission of division by zero by the older mathematicians, Euler for example, has caused untold confusion. We shall see it is entirely superfluous.

Some Properties of the System R

31. The system R, which we have just formed, is made up of the totality of positive and negative integers and fractions, and also zero. It is called the system of rational numbers; any element in it being called a rational number. The elementary arithmetical properties of these numbers having been established, there is no further occasion to employ the special notations (a, b) and $\{a, b\}$; we shall, instead, employ the customary ones. Furthermore, we shall represent for the rest of this chapter the numbers in R indifferently by Greek and Latin letters $a, b, c, \dots a, \beta, \gamma, \dots$

For the sake of completeness we now proceed to deduce a few properties of R, although the reader is probably familiar with them.

32 The system R is invariant with respect to the four rational operations

This simply means that the addition, subtraction, multiplication, and division of any two elements of R, division by 0 of course excluded always leads to an element in R

We saw this is not true for the systems ? and ?

33 1 The system R 18 dense

This term, taken from the theory of aggregates, which we shall take up later, simply means that between any two numbers a, b in R, exists a third and hence an infinity of numbers

For, let

$$a = \frac{a_1}{a_2}, \ b = \frac{b_1}{b_2},$$

and say a>b

$$d = a_1b_2 - a_2b_1$$

18 an integer ≥1

of numbers of R between a, b

Let e be a positive integer By taking it large enough, we can make

$$ed > n$$
,

where n is an arbitrarily large positive integen Let h be any integer, such that

 $ea_2b_1 < h < ea_1b_2$

Then

$$\frac{h}{eb_1b_2}$$

hes between a, b and represents at least n numbers

2 The system 3 is not dense. For, if we take a=n and b=n+1, no element of 3 has between a and b

no element of 3 hes between a sin of the from this results a remark-the difference between 3 and R. After any element n of 3 follows a certain next element v.v.n+1. Not so in R. If a is any number of R there exists no next number to a for a for

34. 1. The system R is an Archimedian system. That is, there is no positive number a in R so small but that some multiple of a, say na, is greater than any prescribed positive number b of R.

For, let

$$a = \frac{a_1}{a_2}$$
.

Let us choose n so large that

$$n > a_2 b$$
.

Then

$$na = \frac{na_1}{a_2} > \frac{a_1a_2b}{a_2} > a_1b \ge b.$$

2. Let a be an arbitrarily large number of R; there exists a positive integer n, such that a/n < b, where b is arbitrarily small.

For, by 1, there exists a positive n, such that

nb > a.

Hence

$$a/n < b$$
.

35. Let us lay off the numbers of R on a right line L, just as is done in analytic geometry.

Thus, having chosen an arbitrary point O as origin, and an arbitrary segment OU as the unit of length, to the positive number p in R, corresponds the point P on L to the right of O, and at a distance p from O. To the negative number -p, corresponds the point Q, lying to the left of O, and such that $\overline{OQ} = p$. To zero corresponds the origin O.

Let a, b, c, \cdots be numbers of R, to which correspond the points A, B, C, \cdots on L. If a < b, the point B lies to the right of A; if a < b < c, the point B lies between A and C.

The point A, corresponding to the number a, is called the representation or image of a.

The points corresponding to the numbers in R we call rational points.

Then, since R is dense, the aggregate \mathfrak{A} formed of the totality of rational points is also dense. That is, if P, Q be any two points

of M, there he an infinity of points between P, Q which belong to II

Furthermore, if P be any point of M, there is no next point to P This representation of the numbers of R by points on a right line is of great assistance to us in our reasoning, as we shall see

Some Inequalities

36 We have seen in 29, 4 that every number a ≠0 in R. may be written

$$a = \pm a_0$$

where as is a positive number

The numerical or absolute value of a is a,, and is denoted by

We have thus.

ial

We also set

 $|a| = a_a$ |0| = 0

For example

1-11-1 I+ # = # .

18-71=17-31=4

37 1 We have now the following fundamental relations

$$|a|=|-a|, \qquad (1$$

$$|a-b|=|b-a|, \qquad (2)$$

$$|a\pm b| \le |a+|b|, \tag{3}$$

$$|a\pm b|\lesssim ||a_i-|b||$$
 (4

$$\{ab\} = \{a\} \{b\},$$
 (5)

$$\left|\frac{a}{b}\right| = \frac{|a|}{|b|}$$
 $b \neq 0$ (6)

They are readily proved For example, consider 3)

There are various cases, according as a, b are positive, negative, or zero. We treat one specimen case.

Let
$$a > 0$$
, $b < 0$. Let $b = -b_0$, $b_0 > 0$.
Then $a + b = a - b_0$, $a - b = a + b_0$.
If $a > b_0$, $|a + b| = |a - b_0| = a - b_0 < a + b_0 = |a| + |b|$.
If $a < b_0$, $|a + b| = |a - b_0| = b_0 - a < a + b_0 = |a| + |b|$.
 $|a - b| = |a + b_0| = a + b_0 = |a| + |b|$.

Which establishes 3) for this case. The other cases are treated similarly.

2. By repeated applications of 3), 5) we get

$$|a_1 \pm a_2 \pm \cdots \pm a_m| \le |a_1| + \cdots + |a_m|;$$
 (7)

$$|a_1 \cdot a_2 \cdots a_m| = |a_1| |a_2| \cdots |a_m|.$$
 (8)

3. Let
$$A > 0$$
, and $|a| < A$. (9)

Then from 9) follows

$$-A < \alpha < A; \tag{10}$$

and conversely from 10) follows 9).

38. 1. An important relation is the following:

Let
$$|a-b| < A$$
, $|b-c| < B$. (1)

Then
$$|a-c| < A+B.$$
 (2)

For, from 1) we have, by 37, 3,

$$-A < a - b < A;$$

$$-B < b - c < B.$$

Adding,

$$-(A+B) < a-c < A+B,$$

which gives 2).

2. A special but common case of the above is when A=B; then

$$|a-c|<2A. (3$$

We shall say that 2) or 3) is obtained from 1) by adding.

39. It will be useful to bear in mind the geometric interpretation or image of certain inequalities which recur constantly in the following. Let a be an arbitrary rational number

On either side of the point a let us mark off points a-b, a+b, at a distance b from a. The rational numbers x whose images fall in the interval a-b, a+b, evidently satisfy the relation

 $-b \le x - a \le b$

$$a-b \le x \le a+b$$
, or what is the same.

That is, z satisfies the inequality

$$|x-a| \le \delta$$
 (1

Conversely, the images of the rational numbers z which satisfy

1) lie in the interval a-b a+bSimilarly, the images of the rational numbers x which satisfy

he in the interval a, a+b, while those corresponding to

$$0 \le a - x \le b$$

he in a - b. a

and is denoted by

Rational Limits

40 In the next chapter we shall have a good deal to say of infinite sequences and their limits. We proceed to define them as far as rational numbers are concerned.

Let A be a set of rational numbers such that

1º It is determined whether a given number belongs to A or not

2° There is a first number a_i of the set, a second number a_2 , and in general, after each a_i follows a certain number a_{i+1}

and in general, after each a_s follows a certain number a_{n+1} .

The set A is then called an infinite sequence or simply a sequence,

$$A = a_1, a_2,$$
 or by $A = \{a_n\},$

EXAMPLES

41. 1. If we take $a_n = n$, $A = 1, 2, 3, \dots = \{n\}$ is a sequence.

2. If we take $a_n = \frac{1}{n}$, we get a sequence

$$A = 1, \frac{1}{2}, \frac{1}{3}, \dots = \left\{\frac{1}{n}\right\}$$

3. If $a_n = 1$, we get a sequence

$$A = 1, 1, 1, 1, \dots = \{1\}.$$

4. Let A consist of the rational numbers lying in the interval 0, 1, arranged in order of magnitude.

This set A is not a sequence. For, although it is perfectly determined what numbers belong to A, and although there is a first element $a_1 = 0$, there is no second element, no third element, etc., by 33, 2. Thus, while condition 1° is satisfied, condition 2° is not.

42. 1. We define now the term limit.

Let l be a fixed rational number. We say: l is the limit of the sequence $A = \{a_n\}$, when for each positive rational number ϵ , small at pleasure, there exists an index m, such that

$$|l - \alpha_n| < \epsilon \tag{1}$$

for every n > m.

In symbols we write

$$l = \lim a_n;$$

we also use the shorter forms

$$l = \lim a_n$$
, or $a_n \doteq l$,

when no confusion can arise.

We shall also employ at times the symbol

$$l=\lim_{A}a_{n}$$
.

When l is the limit of A, we say A is a convergent sequence, and that a_n converges to l as a limit.

2. Notation. We shall find it extremely convenient to employ the following abbreviation:

$$\epsilon > 0, m, |l - a_n| < \epsilon, n > m$$
 (2)

to mean that, for each positive rational ϵ there exists an index m, such that $|l-a_n| < \epsilon$ for every n > m,

The reader should therefore repeat the italics often enough to himself to be able to read the line of symbols 2) without hesitation.

8 The reader should observe that from 2) we can conclude also that for each positive M there exists an m', such that

$$|l-a_n|<\frac{\epsilon}{M}, \qquad n>m^{\epsilon}.$$

If, therefore, {a, } has the rational limit I, we can write

$$\epsilon > 0$$
, m , $|l - a_n| < \frac{\epsilon}{M}$, $n > m$ (3)

We have, of course, changed the notation slightly in 3) by dropping the accent of m'

43 The graphical interpretation of this definition will prove most helpful in our subsequent reasoning

Let us lay off the points on our axis, corresponding to the numbers a_n also the point corresponding to l. On either side of l lay off the points $l - \epsilon$, $l + \epsilon$. These determine an interval, marked heavy in the figure, which we shall call the ϵ interval.

If now l is the limit of the acquence A there must exist for each little ϵ interval, an index m, such that the images of all the numbers a_{n+1} a_{n+2} fall within the ϵ interval. See 39

In general, as e is taken smaller and smaller, the index m increases The definition, however, only requires that for each given e there exists some corresponding m such that 42, 1) holds for every n greater than this m

44 Another useful graphical interpretation of the definition of a limit is the following

We take two axes x, y as in analytic geometry. On the x-axis mark off points 1, 2, 3, \cdots at equal distances apart. Lay off the numbers a_1 , a_2 , a_3 , \cdots as ordinates on lines through the points 1, 2, 3, \cdots parallel to the y-axis. (See Fig.) These points we may consider as the images of the numbers a_n . On either side of the line y = l, draw parallel lines at a distance ϵ from it. We get then a band, shaded in the figure, which we shall call the ϵ -band.

Then, if l is the limit of A, there exists for each ϵ an index m, such that the images of all the numbers a_{m+1} , a_{m+2} , ... fall within the corresponding ϵ -band.

1.
$$A = \left\{\frac{1}{n}\right\}; \lim a_n = \lim \frac{1}{n} = 0.$$

2.
$$A = \left\{1 - \frac{1}{n}\right\}; \lim \left(1 - \frac{1}{n}\right) = 1.$$

3.
$$A=1, -\frac{1}{2}, +\frac{1}{3}, -\frac{1}{4}, \cdots a_n = (-1)^{n+1} \frac{1}{n}$$
; $\lim a_n = 0$.

The reader will find it helpful to construct the graphs, explained in 43, 44, for each of these sequences.

46. If it is known of two rational numbers p, q, that $|p-q| < \epsilon$, however small $\epsilon > 0$ may be taken, then p = q.

For, if $p \neq q$, say p > q, then p - q is a definite positive rational number; call it d. Then |p - q| is not < d, and this contradicts the hypothesis. Hence p = q.

47. A rational sequence $A = \{a_n\}$ cannot have two rational limits l, l'. For, since $a_n \doteq l$, we have by definition,

$$\epsilon > 0, m_1, |l - a_n| < \epsilon, n > m_1.$$
 (1)

Also, since $a_n \doteq l'$, we have

$$\epsilon > 0$$
, m_2 , $|l' - a_n| < \epsilon$, $n > m_2$. (2)

Let $m > m_1, m_2$; then from 1), 2) follows

$$\epsilon > 0, m, |l - a_n| < \epsilon, n > m.$$
 (3)

$$\epsilon > 0$$
, m , $|l' - a_n| < \epsilon$, $n > m$. (4)

(a

(2

• When

Similarly

we shall often set more shortly

may be written more shortly

The mequalities 3), 4), holding now for the same m, we can add them, and get, by 38, 3), 11-11-20

But since e is small at pleasure, so is 2 e The inequality 5) gives, by 46, I = I'

48 If the rational sequence is, has a rational limit I, there exists an index m. such that

δ<α.<ε. n>m. where b is any rational number < L and c any rational number > l

For, since a. = L €>0, m, |1-a|<€ n>m

1-4<0.<1+4 Since e is arbitrarily small, we can take it so small that

1-€>8. 1+€<¢

Then 2) gives 1)

49 Let the two sequences [a,], [b,] have the rational limits a, b

respectively Then $\lim_{a \to b} (a + b) = a + b$, $\lim_{a \to b} (a - b) = a - b$

For, $|(a+b)-(a_a+b_a)|=|(a-a_a)+(b-b_a)|$

<1a-a1+16-61 11

by 37 3)

Since $a_{\bullet} = a$ we have

 $\epsilon > 0$, m', $|a-a_{\epsilon}| < \epsilon/2$ n > m'.

Since b = b we have

(2

2>0, m". 16-6.1<e/2 n>m" (3

4>64>64>6

5>6 c d -

a≠0 0≠0 c≠0--

a b c - ±0

By choosing m so large that m > m', m'', we can suppose 2), 3) hold for the same m "

Then 1) becomes, using 2), 3),

$$|(a+b)-(a_n+b_n)|<\frac{\epsilon}{2}+\frac{\epsilon}{2}=\epsilon.$$
 $n>m.$

This states that

$$\lim (a_n + b_n) = a + b.$$

Similarly, we prove the other half of our theorem.

50. If the two sequences $\{a_n\}$, $\{b_n\}$ have the rational limits a, b respectively, then

 $\lim a_n b_n = ab. (1$

For,

$$d_n = ab - a_nb_n = a(b - b_n) + b_n(a - a_n).$$

$$|d_n| \le |a| |b - b_n| + |b_n| |a - a_n|, \tag{2}$$

by 37, 3), 5).

Since $b_n \doteq b$, we have, by 48,

$$|b_n| < B$$
. $n > m'$.

Also, by 42, 3,

$$|b-b_n|<\frac{\epsilon}{2|a|}$$
 $n>m''$.

Since $a_n \doteq a$, we have, by 42, 3,

$$|a-a_n|<\frac{\epsilon}{2B}$$
 $n>m'''$.

Evidently by taking m large enough, we can use the same m in these three inequalities.

Then they give in 2)

$$|d_n| < |a| \frac{\epsilon}{2|a|} + B \cdot \frac{\epsilon}{2B} = \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon,$$

which proves 1).

51. Let the two sequences $\{a_n\}$, $\{b_n\}$, have the rational limits a, b, respectively. Let b and $b_n \neq 0$.

Then

$$\lim \frac{a_n}{b_n} = \frac{a}{b}.$$

For,

Since $\delta \neq 0$, $|\delta| > 0$ Let B be a rational number, such that

0 < B < | b|

Then by 48, there exists an m such that

$$|b_{\bullet}| > B$$
 $n > m$ (3)

Also, by 42, 3,

$$\epsilon > 0$$
, $m |b-b_a| < \frac{\epsilon |b|B}{2|a|}$ $n > m$ (4)

$$\epsilon > 0$$
, $m \mid \delta - \delta_a \mid < \frac{5(0) \Delta}{2|a|}$ $n > m$ (4)
 $\epsilon > 0$, m , $|a - a_a| < \frac{\epsilon \Delta}{2}$ $n > m$ (5)

(2

By taking m large enough, we can use the same m in these inequalities Putting 3) in 2) we get

$$|d| < \frac{|a|}{|b|B} b - b_a| + \frac{|\alpha - a_a|}{B}$$

$$< \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon, \text{ by 4), 5),}$$

which proves 1)

CHAPTER II

IRRATIONAL NUMBERS

Insufficiency of R

52. Although the system of rational numbers R is dense, and so apparently complete, it is easy to show that it is quite insufficient for the needs of even elementary mathematics.

Consider, for example, the length δ of the diagonal of a unit square. This length is defined by the equation

$$\delta^2 = 2. \tag{1}$$

We can show there is no number in R which satisfies 1). For, suppose

 $\delta = \frac{a}{b}$

where a, b are two positive integers, which we can take without loss of generality, relatively prime.

Then 1) gives

 $a^2=2b^2.$

Let p be any prime factor of b. It is then a divisor of a^2 , and so of a. Thus a and b are both divisible by p. They are thus not relatively prime, unless p = 1.

Thus b=1; and δ is an integer. But obviously there is no integer whose square is 2.

53. 1. A similar reasoning shows that

 $\sqrt[n]{a}$

does not lie in R, unless a is the nth power of a rational number.

The numbers

can be shown to be irrational, the numbers

log x, ex, an x, tan x

are in general not rational

2 Let us show that

$$l = \log 5,$$

the base being 10 does not lie in R If I were rational we should have

 $l = \frac{a}{b}$

where a bare integers

Then

rational numbers

$$10^4 = 5$$
 $10^4 = 5^4$ (1

(A

Obviously I cannot be negative we can thus suppose a b>0

Now any integral positive power of 10 is an integer ending in
0 while any integral positive power of 5 ends in 5

Thus 1) requires that a number ending in 0 should equal a number ending in 5 which is absurd. Hence I is not rational

Cantor s Theory

54 1 The preceding remarks above clearly the necessity of forming a more comprehensive system of numbers than R. How this may be done in various ways has been shown by Weierstrass, Cantor, Dedekind, Hilbert and others

We adduce now certain considerations which lead up to Cantor's theory

We have seen no rational number exists which satisfies the equation $x^2=2$ (1

It is however possible to determine an infinite sequence of

 a_1 a_2 a_2

such that hm a. = 2

The method we now give for finding such a sequence A has no practical value; it has, however, theoretical importance.

For a_1 , we take the greatest integer, such that

$$a_1^2 < 2$$
.

In the present case, $a_1 = 1$.

From the numbers

$$a_1 + \frac{1}{10}, \ a_1 + \frac{2}{10}, \ \cdots \ a_1 + \frac{9}{10},$$
 (2)

we take for a_2 the number whose square is < 2, while the next number of 2) gives a square > 2.

Suppose

$$a_2 = a_1 + \frac{\alpha_1}{10}$$

Then

$$a_2^2 < 2 < (a_2 + \frac{1}{10})^2$$

From the numbers

$$a_2 + \frac{1}{10^2}, \ a_2 + \frac{2}{10^2}, \ \cdots \ a_2 + \frac{9}{10^2},$$
 (3)

we take for a_3 the number whose square is <2, while the next number of 3) gives a square >2.

Suppose

$$a_3 = a_2 + \frac{a_2}{10^2}$$

Then

$$a_3^2 < 2 < \left(a_3 + \frac{1}{10^2}\right)^2$$

We may proceed in this way without end, and get thus an infinite sequence of rational numbers,

$$a_{1};$$

$$a_{2} = a_{1} + \frac{\alpha_{1}}{10};$$

$$a_{3} = a_{2} + \frac{\alpha_{2}}{10^{2}} = a_{1} + \frac{\alpha_{1}}{10} + \frac{\alpha_{2}}{10^{2}};$$

$$a_{4} = a_{3} + \frac{\alpha_{3}}{10^{3}} = a_{1} + \frac{\alpha_{1}}{10} + \frac{\alpha_{2}}{10^{3}} + \frac{\alpha_{3}}{10^{3}};$$

$$\vdots$$

$$a_{n} = a_{n-1} + \frac{\alpha_{n-1}}{10^{n-1}} = a_{1} + \frac{\alpha_{1}}{10} + \frac{\alpha_{2}}{10^{2}} + \dots + \frac{\alpha_{n-1}}{10^{n-1}};$$

By actual calculation we find the numbers

 a_1 a_2 a_3 a_4

2 We show now that

For, from

$$a_n^2 < 2 < \left(a_n + \frac{1}{10^{n-1}}\right)^2$$

we have

$$0 < 2 - a_a^2 < \left(a_a + \frac{1}{10^{n-1}}\right)^2 - a_s^2$$

12-a21<e

$$|2 - a_n^{-1}| < \frac{3}{10^{n-1}} + \frac{1}{10^{2(n-1)}}$$

Obviously now, for each rational $\epsilon > 0$ we can find an m such that

Then

$$\lim a^2 = 2$$

12 > 172

lim α_s²=

55 I The method given in 54 for forming the sequence a_1 , a_2 , a_3 admits a simple graphical interpretation

We first divide the indefinite right line L into unit segments, a_1 is end point of one of these segments. In the present case $a_1 = 1$

We next divide the segment 1, 2 into 10 equal parts, a_2 is the end point of one of these segments. In the present case $a_4 = 1.4$

We next divide the segment 1 4, 15 into 10 equal parts, a₅ is the end point of one of these segments. In this way, we continue subdividing each successive little interval or segment into 10 smaller parts, without end We observe that each little segment is contained in the immediately preceding one, and therefore in all preceding ones.

Also, that the lengths of these segments form a sequence

$$1, \frac{1}{10}, \frac{1}{10^2}, \frac{1}{10^3}, \cdots$$

whose limit is zero.

56. 1. The method of 54 may be used to find an infinite sequence of rational numbers a_1, a_2, a_3, \cdots

which more and more nearly satisfy the equation

$$10^z = 5$$
,

which defines log 5.

We find:

$$a_1 = 0$$
, $a_2 = .6$, $a_8 = .69$, $a_4 = .698$, ...

2. The same method may evidently be applied to any problem which defines an *irrational* number. In each case it leads to a sequence of rational numbers

$$a_1, a_2, a_3, \dots$$
 A

such that

- 1°. Each number a_n satisfies more nearly than the preceding ones the conditions of the problem.
- 2°. For each positive rational ϵ , arbitrarily small, there exists an index m, such that

$$|a_n - a_r| < \epsilon$$

for every $n, \nu \geq m$.

57. Regular Sequences. 1. It is this second property of the sequences A, that Cantor seizes on to construct the elements of his number system. We lay down now the following definitions.

Any infinite sequence of rational numbers

$$a_1$$
, a_2 , a_3 , ...

which has property 2° in 56 is called regular.

As in 42, 2, we shall indicate this property by the abbreviated notation:

$$\epsilon > 0, \quad m, \quad |a_n - a_\nu| < \epsilon, \quad n, \nu \ge m.$$
 (1)

 Every regular sequence defines a number, which we represent by the symbol

$$a = (a_p, a_p, a_p)$$

The totality of such numbers forms a number system, called the system of real numbers

We shall denote it by M, which may be read German R.

For the convenience of the reader, we shall denote in this chap ter the new numbers, $i \in the numbers in \Re$, by the Greek letters a, β, γ , , while the Latin letters a, b, c, denote numbers in the old system R

To see if a given sequence is regular, we must see if the inequalities 1) are satisfied. For this reason we shall speak of these inequalities as the emilest

8 The am test is equivalent to the following.

$$\epsilon > 0$$
, m , $|a_s - a_n| < \epsilon$, $n > m$. (2)

The difference between 1), 2) being that in $|a_n-a_n|$, only one index, n, varies

For, when 1) holds, 2) is satisfied For we pass from 1) to 2) by setting v = m in 1)

Conversely of 2) holds, 1) as satisfied

For, since e in 2) is small at pleasure, let us take

Then 2) gives

$$|a_n - a_m| < \frac{\sigma}{\tilde{q}}$$
 $n > m$.

Also

$$|a_r - a_m| < \frac{\sigma}{0}$$
 $r \ge m$.

Adding the inequalities, we get, by 38, 3),

$$|a_n - a_n| < \sigma$$
, $n, \nu > m$

which is 1)

4. We observe finally that we may replace $n, \nu \ge m$ in 1) by $n, \nu > m$.

For, if $|a_n - a_n| < \epsilon$, (3)

for every $n, \nu \ge m$, it is true for every $n, \nu > m$. Conversely, if 3) is true for every $n, \nu > m$, it is true for every $n, \nu \ge m + 1$. We would therefore in 1) replace m by m + 1.

58. EXAMPLES

1. That the sequences A, defined in 54, are regular, is readily shown. We have

$$a_n = a_1 + \frac{\alpha_1}{10} + \dots + \frac{\alpha_{n-1}}{10^{n-1}}$$

$$a_{\nu} = a_1 + \frac{\alpha_1}{10} + \dots + \frac{\alpha_{\nu-1}}{10^{\nu-1}}$$

For simplicity, suppose $\nu > n$;

then

$$a_{\nu} - a_n = \frac{\alpha_n}{10^n} + \frac{\alpha_{n+1}}{10^{n+1}} + \dots + \frac{\alpha_{\nu-1}}{10^{\nu-1}} < \frac{1}{10^{n-1}},$$
 (1)

as the considerations of 55 show.

If we choose m so large that

$$\frac{1}{10^{m-1}} < \epsilon$$

then, by 1),

$$a_{\nu}-a_{n}<\epsilon$$
. $n, \nu\geq m$.

The ϵ, m test is therefore satisfied.

2. Consider the sequence

$$\frac{1}{1}$$
, $-\frac{1}{2}$, $\frac{1}{3}$, $-\frac{1}{4}$, ...

Here

$$|a_n - a_\nu| = \left|\frac{1}{n} \pm \frac{1}{\nu}\right| = \frac{1}{n} + \frac{1}{\nu}.$$
 (2)

If we take now

$$m > \frac{2}{\epsilon}$$

then

$$\frac{1}{n} + \frac{1}{\nu} < \frac{1}{m} + \frac{1}{m}, \quad n, \nu > m.$$

Hence 2) gives

$$|a_n - a_{\nu}| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon.$$

3. Consider the sequence

Here

$$\alpha_n - \alpha_p = 1 - 1 = 0,$$

and this sequence evidently satisfies the ϵ, m test, and is therefore regular.

4. Consider 1 -1 1 -1

Here | 1a. - a.1 = 0 or 2

Evidently no m exists such that

]a_ - a_)< e = n, +>=.

The sequence is thus not regular

5 Consider

5 Consider 1 2 3 4 ...
Here (a.-a.-la-e)

and the con test is obviously not satisfied. The sequence is therefore not regular

59 For any regular sequence of rational numbers an az. there

exists a positive number M such that

|0_1|< M n=1, 2, 3, (1)

For, the sequence being regular

6>0 m la-a-les n>

Hence $a_{-} = \epsilon < a_{-} < a_{-} + \epsilon$

Let M be taken greater than any of the m + 2 numbers

 $|a_1| |a_2| |a_n|, |a_n + \epsilon| |a_n + \epsilon|$

Then 2) proves 1)

60 The elements of \Re have as yet no arithmetic properties, these we proceed now to assign, employing the method already used in the systems \Re and R

(2

Our first step is to place R in relation to R

Let $u = (a_1 \ a_2)$

be an element of R If there exists a rational number a, such that

 $\lim a_n = a$

we say z = a

61 1 Every number a of R her in R For, consider the sequence

a+1, a+1, a+1,

This sequence is regular, since

$$a_n - a_{\nu} = \frac{1}{n} - \frac{1}{\nu}.$$

The number $\alpha = (a+1, a+\frac{1}{2}, a+\frac{1}{3}, \cdots)$

therefore lies in R.

On the other hand, $a_n \doteq a$.

Hence $\alpha = a$.

2. Let a_1, a_2, \dots be any sequence of rational numbers, having 0 as limit; then

$$0=(\alpha_1,\,\alpha_2,\,\cdots).$$

In particular, $0 = (1, \frac{1}{2}, \frac{1}{3}, \cdots)$ $= (-1, -\frac{1}{2}, -\frac{1}{3}, \cdots)$ $= (1, -\frac{1}{2}, \frac{1}{3}, -\frac{1}{4}, \cdots)$ $= (0, 0, 0, \cdots).$

62. 1. We define now the terms equal, greater than, less than. The object of this is simply to arrange or order the elements of R. Let

$$\alpha = (a_1, a_2, \dots), \ \beta = (b_1, b_2, \dots).$$

We say

$$\alpha = \beta$$
, when $\lim (a_n - b_n) = 0$; (1)

or, what is the same thing, when

$$\epsilon > 0, m, |a_n - b_n| < \epsilon. n > m.$$
 (2)

2. We say $\alpha > \beta$ when there exists a positive rational number r and an index m, such that

$$a_n - b_n > r. \qquad n > m. \tag{3}$$

We say similarly, $\alpha < \beta$, if

$$b_n - a_n > r, \qquad n > m. \tag{4}$$

 $a_n - b_n < -r. ag{5}$

3. Numbers of \Re which are > 0 are called positive; those < 0 are negative.

40

63 It can be shown that from this definition of equality and inequality the usual properties of these terms can be deduced. For example,

For, setting

If
$$\alpha = \beta$$
, $\beta = \gamma$, then $\alpha = \gamma$.

$$a = (a_1, a_2, \dots)$$

$$\beta = (b_1, b_2, \dots),$$

$$\gamma = (c_1, c_2, \dots),$$

we have SIDCE

$$a_n \sim c_n = (a_n - b_n) + (b_n - c_n) = 0$$

$$a_n - b_n = 0$$
, $b_n - c_n = 0$, by hypothesis

64 If $a = (a_1, a_2, a_3, a_4, a_3, a_4, a_5)$ we say (a_1, a_4, a_5, a_5) and (at' a.,) are different representations of the same number a Every number a in R admits an enfinity of representations

In fact, there are obviously an infinity of rational sequences

21, 2, 2, having zero as limit

Then

$$(a_1+z_1,a_2+z_2)$$

represent an infinity of representations of a

65 1 We wish to apply the definition of 62 to the case that one of the members, say β , is a rational number δ

Let a = b.

For $\beta = \delta$, we can take the representation

$$\beta = b \neq (b, b, b)$$

 α

Then 62, 1) requires that

$$hm(a_n-b)=0;$$

whence

$$hm a_- = b$$

Thus the definitions of 60 and 62 are in accord for this case.

2. Let $\alpha > b$.

Since $b_n = b$ by 1), the relation 62, 3) becomes here

$$a_n - b > r, \qquad n > m. \tag{2}$$

Let a < b.

Then

$$b - a_n > r, \qquad n > m. \tag{3}$$

or

$$a_n - b < -r. (4$$

3. If $\alpha = (a_1, a_2, \dots) > 0$, there exists an index m, and two positive rational numbers A, B, such that

$$A < a_n < B; \qquad n > m. \tag{5}$$

and conversely.

For, set b = 0, then 2) gives, replacing r by A,

$$a_n > A > 0. \qquad n > m. \tag{6}$$

On the other hand, 59 gives

$$|a_n| = a_n < B. \qquad n > m. \tag{7}$$

From 6) and 7), we have 5). The second half of the theorem is obvious, by 2.

4. Similarly, we have

If $a = (a_1, a_2, \dots) < 0$, there exists an index m, and two negative rational numbers -A, -B, such that

$$-A < a_n < -B;$$
 $n > m$.

and conversely.

5. From 3 and 4 we have

If $\alpha = (a_1, a_2, \dots) \neq 0$, there exists an index m, and two positive numbers A, B, such that

$$A < |a_n| < B; \quad n > m.$$

6. In any number $\alpha = (a_1, a_2, \dots) \neq 0$, the constituents a_n finally have one sign.

This follows at once from 3 and 4.

65 1 Let
$$a = (a_1, a_2)$$
)

If $a_a \lessgtr a, n > m$ (1

Then $a \lessgtr a$ (2

For, suppose a < a Then, by 65, 2, there exists an r > 0, and an m, such that

Hence $a-d_n>r$ n>m

 $a>a_n+r>a_n$, and therefore

 $a_a < a$,
which contradicts 1) Hence 2) holds

2 Similarly, we show

Let a=(a, a,)

If $a_n \ge a$, n >

then <u>a≤</u>a

67 1 If from the sequence

which defines the number a, we pick out a sequence

 a_n a_n a_n a_n where $a_n < a_n$ a_n , then also

a

(2

The sequence 2) is regular For, since 1) is regular, $\epsilon > 0$, m, $|a_n - a_n| < \epsilon$, n, $\nu > m$

But then $|a_{x}-a_{z}| < \epsilon, \ r, \epsilon < \kappa, \ \epsilon_{x} > m$

Hence 2) is regular, and defines a number β W_{ℓ} show now $a = \beta$ Since 2) contains only a part of 1),

 $i_n \ge n, \quad n = 1, 2, 3, \quad .$ Since 1) is regular,

$$|a_n - a_n| < \epsilon$$
 $n > m$.

Hence, by 62 1, $\alpha = \beta$

2. As corollary we have:

The number $\alpha = (a_1, a_2, \cdots)$ is not altered, if we remove from or add to the numbers in the parenthesis, a finite number of rational numbers.

3. We have also:

If in
$$\alpha = (a_1, a_2, \cdots), \beta = (b_1, b_2, \cdots)$$

$$a_n = b_n, \quad n > m;$$
then $\alpha = \beta.$

68. 1. If $\alpha = (a_1, a_2, \dots) \neq 0$, there cannot be an infinite number of constituents $a_n = 0$.

For, say

Then, by 67, 1,
$$a_{\iota_1} = a_{\iota_2} = a_{\iota_3} = \cdots = 0.$$

$$a = (a_{\iota_1}, a_{\iota_2}, \cdots).$$
But
$$(a_{\iota_1}, a_{\iota_2}, \cdots) = (0, 0, \cdots) = 0.$$

Hence $\alpha = 0$, which is a contradiction.

2. If $\alpha \neq 0$, we can choose a representation (a_1, a_2, \dots) , in which all the $a_n \neq 0$.

For, let
$$\alpha = (\alpha_1', \ \alpha_2', \ \cdots) \tag{1}$$

be any representation of α . By 1, it contains but a finite number of zero. If we leave these zeros out of 1), we do not change the value of α , by 67, 2; and get thereby a representation of α , none of whose constituents are zero.

69. 1. Having ordered the elements of \Re , we proceed to define the rational operations upon them.

Addition.

Let
$$\alpha = (a_1, a_2, \cdots), \beta = (b_1, b_2, \cdots)$$

be two elements of R, different or not; then

$$\alpha + \beta = (a_1 + b_1, a_2 + b_2, \cdots).$$
 (1

To justify this definition of addition, we show first that

 $a_1 + b_1, a_2 + b_2,$ (2) is a regular sequence

Since a_1 , a_2 is a regular sequence, we have

 $\epsilon > 0$, m, $|a_n - a_n| < \epsilon/2$, n, $\nu > m$

Since by. by . is regular, we have

$$\epsilon < 0$$
, $m_1 |b_n - b_r| < \epsilon/2$, $n_1 \nu > m$ (1)

Evidently we can take m so large that 3), 4) hold for the same m

Now

$$\begin{aligned} |(a_n + b_n) - (a_n + b_n)| &= |(a_n - a_n) + (b_n - b_n)| \\ &< |a_n - a_n + b_n - b_n|, \text{ b}; 37, 3), \\ &< \frac{\epsilon}{0} + \frac{\epsilon}{3} = \epsilon, \text{ b}; 3), 4 \end{aligned}$$

Thus 2) is regular, and defines a number

2 We show next that, if a, β are rational numbers, say a = a, $\beta = b$, then $a + \beta$, as defined by 1), is a + b. Since a is a rational number a.

 $\lim a_n = a_1$ by 60

Similarly, $\lim b_a = b$

But $\lim (a_n + b_n) = \lim a_n + \lim b_n = a + b$, by 49.

Thus by 60, $(a_1 + b_1 \ a_2 + b_3) = a + b$

Hence by 1) a+B=a+b

70 1 If $\beta > \gamma$, then $\alpha + \beta > \alpha + \gamma$

Let $\gamma = (c_1, c_n)$ Since $\beta > \gamma$, there exists, by 62, 2, a positive rational number r, such that

Hence, adding a_n , $a_n + b_n > a_n + c_n + r$

 $(a_n+b_n)-(a_n+c_n)>r.$

Hence, by 62, 2, a+B>a+v

2. From 1, we conclude, as in 26, that

If
$$\alpha + \beta = \alpha + \gamma$$
, then $\beta = \gamma$.

71. 1. Subtraction.

This is the inverse of addition; we define it as we did in $\mathfrak F$ and R, viz.: The result of subtracting β from α is the number or numbers ξ , in $\mathfrak R$, which satisfy

 $\alpha = \beta + \xi. \tag{1}$

There is at most one number \xi.

For, suppose
$$\alpha = \beta + \eta$$
. (2)

Then 1), 2) give, by 63,

$$\beta + \xi = \beta + \eta$$

Hence, by 70, 2, $\eta = \xi$.

To show that 1) admits one solution, we prove just as in 69, 1, that

 $a_1 - b_1$, $a_2 - b_2$, ...

is a regular sequence, and thus defines a number

$$\xi = (a_1 - b_1, a_2 - b_2, \cdots).$$

If we put this value of ξ in 1), the equation is satisfied.

For,
$$\beta + \xi = (b_1, b_2, \cdots) + (a_1 - b_1, a_2 - b_2, \cdots)$$

= $(b_1 + a_1 - b_1, b_2 + a_2 - b_2, \cdots)$, by 69, 1)
= $(a_1, a_2, \cdots) = \alpha$.

2. Thus subtraction is always possible in \mathfrak{R} , and is unique. The result of subtracting β from α we represent by $\alpha - \beta$; we have then $\alpha - \beta = (\alpha_1 - b_1, \alpha_2 - b_2, \cdots)$.

3. We represent $0 - \alpha$ by $-\alpha$.

Evidently, $-\alpha = (-a_1, -a_2, -a_3, \cdots).$

We observe that $\alpha + (-\alpha) = 0$; $\alpha + (-\beta) = \alpha - \beta$; $-(-\alpha) = \alpha$. 72 1 If a is positive, — a is negative, and if a is negative, — a is nonlive

For, if $a = (a_1, a_2, a_3) > 0$, we have, by 65, 3,

$$a_{\star} > A > 0$$
 $n > m$

Now
$$-\alpha = (-\alpha_p - \alpha_p), \text{ by 71, 8}$$

Hence, by 1),
$$-4 < -A < 0 \qquad n > m$$

which proves the first part of the theorem The second part is proved similarly

2 All the numbers of $\Re \neq 0$ are of the form a or -a where a is a positive number

a positive number $\neq 0$ We need to consider only the case that β is negative

$$\beta = -(-\beta)$$

and by 1), $-\beta$ is positive

73 1 Multiplication

The product of a by \$ we define by

$$a\beta = (a_1b_1, a_1b_2, \cdots).$$

 $a\beta = (a_1b_1, a_3b_2)$

$$a_1b_1$$
, a_2b_1 , (2)

 α

We have to show that 13 a regular sequence

Let ϵ be a positive rational number, small at pleasure. Then, by 59, there exists a positive M, such that,

$$[a_n], |b_n| < M$$
 $n > m$ (3)

Also, since the sequences $\{a_n\}$, $\{b_n\}$ are regular, we can suppose m in 3) is taken so large that

$$|a_n - a_\nu|$$
, $|b_n - b_\nu| < \frac{\epsilon}{9.85}$ n, $\nu > m$ (4)

$$\begin{aligned} d_n &= a_n b_n - a_\nu b_\nu = a_n (b_n - b_\nu) + b_\nu (a_n - a_\nu). \\ & \therefore |d_n| \gtrsim |a_n| |b_n - b_\nu| + |b_\nu| |a_n - a_\nu|, \text{ by 37,} \\ & < M \cdot \frac{\epsilon}{2M} + M \frac{\epsilon}{2M}, \text{ by 3) and 4).} \end{aligned}$$

$$|d_n| < \epsilon$$

and 2) is regular.

2. If α , β are rational, say $\alpha = a$, $\beta = b$, we show that $\alpha\beta$ as defined in 1) is ab.

For, since α and β are rational,

$$\lim a_n = a$$
, $\lim b_n = b$, by 60.

But then, by 50,

$$\lim a_n b_n = \lim a_n \lim b_n = ab,$$

which states that $\alpha \beta = ab$.

74. 1. The formal laws for addition and multiplication are readily proved. We illustrate this by establishing the associative law of multiplication.

We wish to show that

$$\alpha \cdot \beta \gamma = \alpha \beta \cdot \gamma. \tag{1}$$

We have, by 73. 1),

$$\beta \gamma = (b_1 c_1, b_2 c_2, \cdots).$$

Hence

$$\alpha \cdot \beta \gamma = (a_1, a_2, \cdots)(b_1c_1, b_2c_2, \cdots)$$

 $= (a_1 \cdot b_1 c_1, \ a_2 \cdot b_2 c_2, \ \cdots). \tag{2}$ Similarly,

$$\alpha\beta \cdot \gamma = (a_1b_1 \cdot c_1, \ a_2b_2 \cdot c_2, \ \cdots). \tag{3}$$

Since multiplication is associative in R, the two numbers represented by 2), 3) are identical, which proves 1).

2. As a consequence of the associative law, we have, m, n being positive integers,

$$\alpha^m \alpha^n = \alpha^{m+n}$$

which expresses the addition theorem for integral positive exponents.

75 1 The properties of products, relating to greater than, less than, are readily established for numbers in R

If $\alpha > \beta$, and $\gamma > 0$, then $\alpha \gamma > \beta \gamma$

For, since $\alpha > \beta$, we have, by 62, 2,

$$a_n - b_n > r > 0$$
 $n > m$

Since 7>0, there exists a positive rational number c, by 65, 3, such that

c. >c 25 m

By taking m sufficiently large, we may take the same m in both these meaualities

They give

Then, by 62, 2,
$$a_nc_s - b_nc_n > cr > 0.$$

2 From 1 follows

If $\alpha > 8 > 0$, then

3 From 2 we conclude

If $\alpha, \beta > 0$, and $\alpha^* = \beta^*$, n being a positive integer, then

4 If 0 < a < 1, then a < a

For, from

a<1. we have

3 < a Also

Hence

 $a^3 < a$ Hence in general,

 $a^{n} < a$

76 1 Rule of signs The product of two positive or two negative numbers in R is positive. The product of a positive and a negative number is negative

 $a^3 < a^3$

Let $\alpha > 0$, $\beta > 0$; then $\alpha \beta > 0$.

By 65, 3, there exist two positive numbers A, B, and an index m, such that

$$a_n > A$$
, $b_n > B$. $n > m$.

Hence

$$a_n b_n > AB > 0$$
.

Thus

$$\alpha\beta = (a_1b_1, a_2b_2, \cdots) > 0$$
, by 66.

Let $\alpha > 0$, $\beta < 0$; then $\alpha \beta < 0$

For, by 65, 3, 4,

$$a_n > A$$
, $b_n < -B$. $n > m$.
 $\therefore a_n b_n < -AB < 0$.
 $\alpha \beta < 0$.

Thus, by 66,

In a precisely similar manner, we can treat the other cases.

77. 1. The product of any two numbers in R vanishes when, and only when, one of the factors is zero.

In the product $\alpha\beta$, suppose $\alpha=0$; then $\alpha\beta=0$.

Then

$$\alpha = (0, 0, 0, \cdots), \quad \beta = (b_1, b_2, \cdots).$$

$$\therefore \alpha \beta = (0 \cdot b_1, 0 \cdot b_2, \cdots) = (0, 0, \cdots) = 0.$$

Conversely, if $\alpha\beta = 0$, either α or $\beta = 0$.

This is proved, as in 25.

2. If $\alpha \neq 0$, and $\alpha\beta = \alpha\gamma$, then $\beta = \gamma$.

Proof same as that for 26, 3).

78. 1. Division.

The quotient of α by β is the number or numbers ξ , in \Re , which satisfy

$$\alpha = \beta \xi.$$
 (1

There are two cases, according as $\beta = 0$, or $\neq 0$.

50

Case I $\beta \neq 0$ Since $\beta \neq 0$, we may suppose, by 68, 2 that in

Since $\beta \neq 0$, we may suppose, by 68, 2 that in $\beta = (\delta_1 \ b_2)$

all $\delta_{-} \neq 0$ To find a solution of 1) consider the sequence

It is regular For, $d_{a,b} = \frac{a_b}{b_1} \frac{d_b}{b_2}$ $d_{a,b} = \frac{a_b}{b_1} - \frac{a_b}{b_2} = \frac{a_bb_c - a_bb_a}{b_2} = \frac{a_b(b_c - b_a) - b_a(a_c - a_a)}{b_2}$

Hence $b_n = b_n = b_n b_n$

 $|d_{n,r}| \le \frac{|a_n||b_r - b_n| + |b_n||a_r - a_n|}{|b_n||b_r|} \tag{8}$

(2

By 55, By 65 5, we have $|a_n| < M$ n > m (4)

 $A < |b_n| < B$ n > m (5) By taking m sufficiently large we may suppose it to have the

same value in 4) 5)

Then 4), 5) gives in 3) $|d_{a,c}| < \frac{M|b_c - b_a| + B|a_c - a_a|}{42}$ (6)

Since the sequences $\{a_n\}$ $\{b_n\}$ are regular we may now suppose m taken so large that also

 $|a_r - a_n| < \frac{\epsilon A^2}{2B} |b_v - b_n| < \frac{\epsilon A^2}{2BL} \qquad n, v > m$

Then 6) gives $|d_{n,r}| < \frac{\epsilon}{2} + \frac{\epsilon}{n} = \epsilon$

Since 2) is regular, it defines a number

$$\xi = \begin{pmatrix} a_1 & a_2 \\ \overline{b}_1 & \overline{b}_2 \end{pmatrix}$$

Since

$$\beta \ \xi = (b_1 \ b_2 \) \left(\frac{a_1}{b_1} \ \frac{a_3}{b_3} \ \right)$$

$$=(a_1 \ a_2 \)=\alpha \text{ by 73, 1)},$$

satisfies 1)
 That this is the only solution of 1) follows as in 30, 1, from 77, 2

Case II; $\beta = 0$.

We can reason precisely as we did in 30, 2. Hence, when the divisor $\beta = 0$, division is either impossible or entirely indeterminate. For this reason division by 0 is excluded.

- 2. We have thus this result: in the system \Re , division is always possible and unique, except when the divisor is 0, when division is not permissible.
- 3. The result of dividing α by β , we represent by α/β and have therefore

Since
$$\frac{\alpha}{\beta} = \left(\frac{a_1}{b_1}, \frac{a_2}{b_2}, \cdots\right).$$

$$\frac{1}{\beta} = \left(\frac{1}{b_1}, \frac{1}{b_2}, \cdots\right).$$

This is called the reciprocal of β .

- 79. 1. The system \Re is now completely defined; its elements have been ordered, and the four rational operations upon them have been defined. As a perfect analogy exists between the systems R and \Re , we are justified in calling the elements of \Re numbers. In the future, when speaking of numbers, without further predicate, we shall mean the numbers in \Re . As already stated, they are called real numbers.
- 2. In the ϵ,m test, given in 57, we were obliged at that stage to take ϵ rational. This is now quite unnecessary, and we shall therefore, in the future, suppose ϵ is any positive number in \Re , small at pleasure.
- 80. 1. We have shown in 61 that \Re contains all the numbers of R; but we have not shown that it contains other numbers.

To this end, we show that there is a number α which satisfies

$$x^2 = 2. (1$$

This is easily done. For in 54 we determined a rational sequence $a_1 = 1$, $a_2 = 1.4$, $a_3 = 1.41$, ... (2)

such that

$$\lim a_n^2 = 2. \tag{3}$$

The sequence 2) is regular by 58, 1.

Hence

«=(a., a., ---)

is a number in 92 But, by 73, 1), $a^2 = (a, 1, a, 2, ...)$

Hence 3) shows, by 60, that

$$\alpha^{\lambda} = 2$$
.

Hence & 18 a solution of 1)

2 As we saw in 52 that a is not rational, we have shown there is at least one number in R not in R

But the reasoning we have just applied to \$\sqrt{2}\$ applies equally to Va, when this latter is not rational. There are thus an infinity of numbers in 92 not in R

Some Properties of M

81 If u > 0, there are an unfanty of positive rational numbers < a, and also an infinity of rational numbers > a

If a is rational, the theorem is obviously true by 83.

Let
$$\sigma = (a_1, a_p, \cdot)$$

Then, by 65, 3, $0 < A < a_n < B$ $n > m$. (1)

a > Awe have, by 66, 1, 4 7 A

Since there are an infimity of rational numbers between 0 and the positive rational number A, the first half of the theorem is established

Using the other part of the meguality 1), we prove similarly the rest of the theorem

82 Between α, β, lie an infinity of rational numbers

For, let $a < \beta$, then, by 81, there exist positive rational numbers A, B, d, such that

Let

$$D = B - A$$
;

we can, by 34, 2, determine the positive integer n so great that

$$\frac{D}{n} < d$$
.

Then, at least one of the numbers

$$A+\frac{D}{n}$$
, $A+2\frac{D}{n}$, ... $A+(n-1)\frac{D}{n}$

falls between α and β .

83. 1. The system \Re is Archimedian; i.e. for each pair of positive numbers $\alpha < \beta$ there exists a positive integer n, such that $n\alpha > \beta$.

For, by 81, there exist positive rational numbers

$$a < \alpha, b > \beta.$$

Since the system R is Archimedian [34, 1], there exists an integer n, such that na > b.

But

 $n\alpha > na$, and $b > \beta$.

Hence

 $n\alpha > \beta$.

2. For any pair of positive numbers $a < \beta$ there exists a positive n such that

 $\frac{\beta}{n} < \alpha$.

Proof, as in 34, 2.

84. Between α and β , $\alpha < \beta$, lie an infinity of irrational numbers. That irrational numbers exist, we have shown in 80.

Let i be an irrational number, r a rational number, and n a positive integer.

Then

$$j=\frac{i}{n}, k=i+r$$

are irrational.

For, if j were rational, i=nj is rational. This is a contradiction. Similarly, if k were rational, i=k-r is rational, which is a contradiction.

This established, suppose first that a is rational and positive. Let t be any positive irrational number

Then, by 83, 2, we can take a so large that

But then

$$\frac{1}{n} < \beta - \alpha$$

$$\alpha < \alpha + \frac{1}{n} < \beta,$$

and

is irrational

By 81, there exists a positive rational number r, such that

10008-0

Then

and is irrational

The cases when α , β are one or both negative are now easily treated

85 The system R 12 dense, 1 & between any two numbers of R lie an infinity of numbers

This follows at once from 82 or 84

Numerical Values and Inequalities

86 We have seen, 12, 2, that any number a≠0 can be written

where a is a positive number

We define now, as in 36, the numerical or absolute value of a se + and denote at by [ati

Then by definition

$$|\alpha| \simeq \alpha_1$$

We set also

$$a = a_{j}$$

87. 1. We have now the following fundamental relations:

$$|\alpha| = |-\alpha|; \tag{1}$$

$$|\alpha - \beta| = |\beta - \alpha|; \tag{2}$$

$$|\alpha \pm \beta| \ge |\alpha| + |\beta|; \tag{3}$$

$$|\alpha \pm \beta| \leq ||\alpha| - |\beta||; \tag{4}$$

$$|\alpha\beta| = |\alpha| \cdot |\beta|; \tag{5}$$

$$\left|\frac{\alpha}{\beta}\right| = \left|\frac{\alpha}{\beta}\right|; \qquad \beta \neq 0.$$
 (6)

$$|\alpha_1 \pm \alpha_2 \cdots \pm \alpha_m| \le |\alpha_1| + \cdots + |\alpha_m|; \tag{7}$$

$$|\alpha_1 \cdot \alpha_2 \cdots \alpha_m| = |\alpha_1| \cdot |\alpha_2| \cdots |\alpha_m|. \tag{8}$$

2. From

$$|\alpha| < A$$
.

follows

$$-A < \alpha < A$$
:

and conversely.

3. From

$$|\alpha - \beta| < A, |\beta - \gamma| < B,$$

follows

$$|\alpha - \gamma| < A + B$$
;

or if A = B,

$$|\alpha - \gamma| < 2A$$
.

- 4. As the demonstration of these relations is exactly the same as in 37, 38, we do not need to repeat it.
- 5. If we know of two numbers α , β , that $|\alpha \beta| < \epsilon$ however small $\epsilon > 0$ is taken; then $\alpha = \beta$.

The demonstration is the same as in 46.

88. If
$$\alpha = (a_1, a_2, ...)$$
, then

$$|\alpha|=(|\alpha_1|,|\alpha_2|,\cdots).$$

Since the sequence

$$a_1, a_2, \dots$$

defines a number, it is regular.

Hence

$$\epsilon > 0$$
, m , $|a_n - a_\nu| < \epsilon$. n , $\nu > m$.

lim a = 0.

(1

From this we conclude that the sequence

$$|a_1|$$
, $|a_2|$, ...

regular. For, by 87, 4), $||a_a|-|a_a|| < |a_a-a_a|$.

Hence 1) defines a number

Set $\beta = (|a_1|, |a_2|, \cdots)$

To show that $\beta = \alpha$

First suppose a = 0

Then

Hence $\lim_{t\to\infty} \{a_n^i = 0\}$

Therefore $\beta = 0$, and $\beta = a$

Suppose $a \neq 0$ Then, by 65, 6, the constituents a_a of a are of

one sign, for n > mIf a > 0, a = |a| n > m

Hence $\beta = (|a_1|, |a_2|, \dots, |a_n|, a_{n-1}, a_{n-1}, \dots)$

=a=|a|, by 67, 3.

If a < 0, $a_n = -|a_n|$ n > m

Hence
$$\beta = ([a_1], \dots [a_n] - a_{n+1}, \dots - a_{n+2}, \dots)$$

 $= -(\sim [a_1], \dots \sim [a_n], a_{n+2}, \dots)$
 $= -a, \text{ by 67, 3}$

89 In the following articles we give certain equalities and inequalities which are often useful

Let $0 < \alpha < 1$, then $\frac{1}{1+\alpha} > 1-\alpha$, (1)

$$\frac{1}{1-\alpha}$$
>1+ α . (2

To prove 1), let us suppose the contrary, viz.:

$$\frac{1}{1+\alpha} \overline{\geq} 1 - \alpha.$$

Clearing of fractions,

$$1<1-\alpha^2$$
, or $\alpha^2\leq 0$,

which is a contradiction.

Similarly, we may prove 2).

90. 1. Let
$$\alpha_1, \alpha_2, \dots, \alpha_m > 0$$
 and $P_m = (1 + \alpha_1)(1 + \alpha_2) \dots (1 + \alpha_m)$.

Then
$$P_m > 1 + (\alpha_1 + \dots + \alpha_m). \qquad m > 1.$$

$$P_m > 1 + (\alpha_1 + \dots + \alpha_m) + (\alpha_1 \alpha_2 + \alpha_1 \alpha_3 + \dots + \alpha_{m-1} \alpha_m).$$
 $m > 2.$

In fact,

$$\begin{split} P_2 = & (1+\alpha_1)(1+\alpha_2) = 1 + (\alpha_1+\alpha_2) + \alpha_1\alpha_2 > 1 + (\alpha_1+\alpha_2) \;; \\ P_3 = & P_2(1+\alpha_3) = 1 + (\alpha_1+\alpha_2+\alpha_3) + \alpha_1\alpha_2 + \alpha_1\alpha_3 + \alpha_2\alpha_3 + \alpha_1\alpha_2\alpha_3 \\ > & 1 + (\alpha_1+\alpha_2+\alpha_3) + \alpha_1\alpha_2 + \alpha_1\alpha_3 + \alpha_2\alpha_3 \\ > & 1 + (\alpha_1+\alpha_2+\alpha_3). \end{split}$$

In this way we can continue.

2. Similarly, we can prove:

Let
$$0 < \alpha_1, \alpha_2, \dots \alpha_m < 1$$
, and

$$Q_m = (1 - \alpha_1)(1 - \alpha_2) \cdots (1 - \alpha_m).$$

Then
$$Q_m > 1 - (\alpha_1 + \dots + \alpha_m)$$
. $m > 1$.
 $< 1 - (\alpha_1 + \dots + \alpha_m) + (\alpha_1 \alpha_2 + \alpha_1 \alpha_3 + \dots + \alpha_{m-1} \alpha_m)$. $m > 2$.

91. The demonstration of the following identities is obvious:

$$\frac{1}{1-\alpha} = 1 + \alpha + \alpha^2 + \dots + \alpha^{n-1} + \frac{\alpha^n}{1-\alpha}$$
 (1)

$$\frac{\alpha + \epsilon}{\beta + \delta} = \frac{\alpha}{\beta} + \frac{\beta \epsilon - \alpha \delta}{\beta (\beta + \delta)}.$$

92 Let
$$|\delta_1|$$
, $|\delta_2| < \delta$, and $\beta \neq 0$, let
$$\rho = \frac{\alpha + \delta_1}{2 + \delta_2}$$

Let $\epsilon > 0$ be small at pleasure, we can take $\delta > 0$ so small that

$$\rho = \frac{\alpha}{\rho} + \sigma \quad |\sigma| < \epsilon$$
 (1)

For, by 91, 2,

$$\sigma = \frac{\delta_1 \beta - \delta_2 \alpha}{\beta (\beta + \delta_2)}$$

Hence

$$|\sigma| \leq \frac{\delta(\alpha + \beta)}{(\beta) - \beta(-\delta)}$$
 by 37,

taking 8 so small that

$$|\beta| - \delta > 0$$

by 37, (2

Let

Then 2) gives

$$|\sigma| < \frac{2 \delta q}{l^2}$$

Hence, if we take

$$\delta < \frac{h^2 \epsilon}{2 a}$$

we have 1)

93 Let a₁ a₂ a, be n arbitrary numbers

Let β_1 β_n γ_1 $\gamma_n > 0$ If

$$L \leq \frac{\alpha_1}{\beta_1} \cdot \frac{\alpha_2}{\beta_2}, \quad \frac{\alpha}{\beta_1} \leq G,$$

then

$$L \leq \frac{\gamma_1 \alpha_1 + \dots + \gamma_n \alpha_n}{\gamma_n \beta_1 + \dots + \gamma_n \beta_n} \leq G$$

For, from

2 02, 220

$$\frac{a_1}{\beta_1} \ge L, \qquad \frac{a_n}{\beta_n} \ge L,$$

we have

$$\gamma_1 \alpha_1 \ge \beta_1 \gamma_1 L$$
 $\gamma_4 \alpha_n \ge \beta_4 \gamma_4 L$

Adding, $\gamma_1\alpha_1 + + \gamma_4\alpha_4 > L(\beta_1\gamma_1 + + \beta_4\gamma_4)$,

which gives the first half of 1) The rest of 1) follows similarly

94. 1. Let $\alpha > \beta \leq 0$; and n > 1, a positive integer.

$$n(\alpha - \beta)\beta^{n-1} < \alpha^n - \beta^n < n(\alpha - \beta)\alpha^{n-1}. \tag{1}$$

For, by direct multiplication, we verify

$$\alpha^{n} - \beta^{n} = (\alpha - \beta)(\alpha^{n-1} + \alpha^{n-2}\beta + \alpha^{n-3}\beta^{2} + \dots + \beta^{n-1}).$$
 (2)

In the second parenthesis, replace α by β . Then, since $\alpha > \beta$,

$$\alpha^n - \beta^n > (\alpha - \beta)(\beta^{n-1} + \beta^{n-1} + \cdots n \text{ terms}),$$

or

$$\alpha^n - \beta^n > n(\alpha - \beta)\beta^{n-1}$$

which is a part of 1).

If in 2) we replace β by α , we get the other half of 1).

2. In 1), set
$$\alpha = 1 + \delta$$
, $\delta > 0$, $\beta = 1$, we get
$$(1 + \delta)^n > 1 + n\delta.$$

If we set $\alpha = 1$, $\beta = 1 - \delta$, 1) gives

$$(1-\delta)^n > 1-n\delta.$$

We have thus

$$(1+\alpha)^n > 1 + n\alpha$$
, $\alpha \neq 0$ and ≤ -1 , n positive integer. (3)

3. We observe that 1) can be written

$$\alpha^n > \beta^{n-1} [\beta + n(\alpha - \beta)],$$
 (4)

$$\beta^{n} > \alpha^{n-1} \lceil \alpha - n(\alpha - \beta) \rceil. \tag{5}$$

95. Let $\alpha_1 \cdots \alpha_n$ be any *n* numbers.

$$A_n = \frac{\alpha_1 + \dots + \alpha_n}{n}$$

is called their arithmetic mean.

Let $\alpha_1 \cdots \alpha_n$ be positive, and $P_n = \alpha_1 \cdot \alpha_2 \cdots \alpha_n$.

Then $P_n < A_n^n$, unless the a's are all equal, when $P_n = A_n^n$.

If $\alpha_1 = \alpha_2 = \cdots = \alpha_n$, $A_n = \alpha_1$ and $P_n = \alpha_1^n$.

Hence

$$P_n = A_n^n$$
.

Suppose now the a's are not all equal.

Let
$$n=2$$

We have $a_1a_2 = \left(\frac{a_1 + a_2}{2}\right)^4 - \left(\frac{a_1 - a_2}{2}\right)^3 < \left(\frac{a_1 + a_2}{2}\right)^3.$ Hence

P. < A.3

а

(2

ß

(4

Let n = 24.

Since the
$$e^{ix}$$
 are not all equal, at least two of them, say $e_{p} e_{j}$.

Then

 $e_{j} e_{j} < \left(\frac{e_{j} + e_{j}}{2}\right)^{2}$, and

Hence
$$\begin{aligned} a_2a_i &\leq \left(\frac{a_i+a_i}{2}\right)^3 \\ a_1a_2a_3a_i &< \left(\frac{a_1+a_1}{2}\right)^3 \left(\frac{a_2+a_1}{2}\right)^3. \end{aligned}$$

On the other hand, applying our theorem to

a+a a+a we have

 $\frac{a_1+a_2}{2} \stackrel{a_2+a_3}{=} \left(\frac{a_1+a_2+a_3+a_4}{4}\right)^2.$ Hence I) and 2) give $P_{\bullet} < A_{\bullet}^{A}$

In the same way, we may continue for any power of 2. Let 2n-1 < n < 2n Set \(\mu = 2n, 2n - n = r. \)

We have, by the preceding case,

 $a^{1}a^{1} \cdot a^{2} < \left(\frac{a^{1} + \cdots + a^{2}}{a^{1} + \cdots + a^{2}}\right)^{2}$ Set here

Then 3) gives $a_{n+1} = a_{n+2} = a_n = A_n$.

 $P_{\bullet}A_{\bullet} < \left(\frac{a_{1} + \cdots + a_{n} + \nu A_{n}}{a_{n}}\right)^{n} = A_{\bullet}^{n}$

âlnca $\frac{\alpha_1 + \dots + \alpha_n + \nu A}{\mu} = \frac{nA_n + \nu A}{\mu} = \frac{\mu A}{\mu} = A_{\mu}$ Dividing in 4) by A; we get

P. < 42.

96. From algebra we have the Binomial Theorem,

$$(\alpha + \beta)^{n} = \alpha^{n} + n\alpha^{n-1}\beta + \frac{n \cdot n - 1}{1 \cdot 2}\alpha^{n-2}\beta^{2} + \frac{n \cdot n - 1 \cdot n - 2}{1 \cdot 2 \cdot 3}\alpha^{n-3}\beta^{3} + \dots + \frac{n \cdot n - 1}{1 \cdot 2}\alpha^{2}\beta^{n-2} + n\alpha\beta^{n-1} + \beta^{n}, \quad (1$$

where n is a positive integer.

The binomial coefficients

$$\frac{n\cdot n-1\cdot n-2\cdots n-m+1}{1\cdot 2\cdots m},$$

we denote by

$$\binom{n}{m}$$
.

We have obviously,

$$\binom{n}{n} = 1.$$

$$\binom{n}{m} + \binom{n}{m-1} = \binom{n+1}{m}.$$

If we set $\alpha = \beta = 1$ in 1), we get

$$2^{n} = 1 + \binom{n}{1} + \binom{n}{2} + \dots + \binom{n}{n-1} + \binom{n}{n}$$

If we set $\alpha = 1$, $\beta = -1$ in 1), we get

$$\mathbf{v} = 1 - \binom{n}{1} + \binom{n}{2} - \dots + (-1)^n \binom{n}{n}$$

It is often convenient to set

 $\binom{n}{0} = 1$,

and

$$\binom{n}{m} = 0$$
, if $m > n$.

Limits

97. We extend now the terms sequence, regular sequence, limit, etc., to numbers in \Re . This is done at once; for the definitions given in 40, 42, and 57 may be extended to \Re , by simply replacing the term rational number by number in \Re .

For example, the sequence of numbers in M

$$\alpha_{11} \quad \alpha_{22} \quad \alpha_{23}$$
 (1)

is regular when, for each positive ϵ (not necessarily a rational number now) there exists an index m_i such that

$$|\alpha_a - \alpha_s| < \epsilon$$

for every pair of indices n, v > m

Or in abbreviated form, when

$$\epsilon > 0$$
, m , $|\alpha_n - \alpha_r| < \epsilon$ n , $\nu > m$ (2)

This definition, we see, is perfectly analogous to that given in 57, 1 for regular rational sequences. Evidently the reasoning of 57, 3, 4, can be applied to the sequence 1). Thus the e,m test given in 2 may also be stitled in the form

α, α, α, · ·

$$\epsilon > 0$$
, m , $|\alpha_n - \alpha_m| < \epsilon$, $n > m$.

Similarly, & in the limit of the sequence

when

$$e>0$$
, m , $|\lambda-\alpha_n|< e$, $n>m$. (4)

(3

(1

As before, we write

$$\lambda = \lim s_n$$
, or $\lambda = \lim s_n$

We say also on converges to & or approaches & as limit.

This may be indicated by the notation

98 Let $\lim \alpha_n = a$ and $\lim \beta_n = \beta$

Then $\lim_{x \to a} (a_x \pm \beta_x) = a \pm \beta$:

$$\lim a_{-}\beta_{-} = a\beta_{-}$$
 (2)

If β , β_1 , β_2 , $\cdot \cdot \neq 0$, we have also

and thus does not need to be repeated here.

$$\lim_{R \to R} \frac{\alpha_s}{R} = \frac{\alpha}{R}.$$
 (3)

β β

The demonstration is precisely similar to those of 49, 50, 51;

LIMITS 63

99. We prove now the important theorem:

Let $u = (a_1, a_2, \dots)$, the a's rational; then $\lim a_n = \alpha$.

We must show that

$$\epsilon > 0, m, |\alpha - \alpha_n| < \epsilon, n > m.$$
 (1)

Since the sequence

$$\alpha_1, \alpha_2, \alpha_3, \cdots$$

is regular, we have

$$\sigma > 0$$
, m , $|\alpha_n - \alpha_\nu| < \sigma$, n , $\nu > m$. (2)

Now we can write, by 60,

$$\alpha_n = (\alpha_n, \alpha_n, \alpha_n, \cdots).$$

Hence, by 71, supposing n to be fixed for the moment,

$$\alpha - a_n = (a_1 - a_n, a_2 - a_n, a_3 - a_n, \cdots).$$

By 88,

$$|\alpha - a_n| = (|a_1 - a_n|, |a_2 - a_n|, \cdots).$$

Hence, by 2) and 66, 2,

$$|\alpha - a_n| \leq \sigma$$
.

Thus if we take $\sigma < \epsilon$, we have 1).

100. If a sequence

$$A = \alpha_1, \ \alpha_2, \ \cdots$$

has a limit λ , A is regular.

For, by definition,

$$\epsilon > 0$$
, m , $|\lambda - \alpha_n| < \epsilon/2$, $n > m$.

$$|\lambda - \alpha_{\nu}| < \epsilon/2, \quad \nu > m.$$

Adding, by 87, 3,

$$|\alpha_n - \alpha_{\nu}| < \epsilon$$
. $n, \nu > m$.

Hence A is regular, by 97.

101. 1. Conversely, if $A = \alpha_1, \alpha_2, \cdots$ is a regular sequence, there exists one, and only one, number α , such that

$$\lim \alpha_n = \alpha. \tag{1}$$

To show that A cannot have two limits, we need only to repeat the reasoning of 47.

We show now A has a limit

Let
$$\delta_p \delta_p \delta_p \dots$$
 (2)

be a sequence of positive numbers whose limit is 0. We choose the 5's new, such that

$$a_n \simeq a_n + \delta_n$$
, $n = 1, 2, \cdots$ (8)

are rational. This is evidently possible by 82. The sequence

For,
$$a_s - a_r = n_s - a_r + (\delta_s - \delta_r)$$
. (5)

Since A is regular,

$$\epsilon > 0$$
, m , $|\alpha_{\epsilon} - \alpha_{\epsilon}| < \frac{\epsilon}{2}$, n , $\nu > m$. (6)

Since, by 100, the sequence 2) is regular,

$$|\delta_{\bullet} - \delta_{\rho}| < \epsilon/2$$
 $n, \nu > m$ (7)

In the inequalities 6), 7), we may take m the same. Then 5), 6), 7) give $|a_1 - a_2| \le |a_1 - a_2| + |\delta_1 - \delta_2|$

Hence 4) is regular.

We set $a = (a_1, a_3 -)$. Then, by 97.

But, by 3), $\lim a_s = a$

Hence, by 98.

 $\lim a_s = \lim a_s - \lim \delta_s$

= ¢

2. As a result of 1 and 100, we have:

In order that a sequence ap ap - . has a limit, it is necessary and sufficient that it is regular.

102. Let $A = \alpha_1, \ \alpha_2, \cdots$ be a sequence. Let us pick out of A a sequence $B = \alpha_1, \ \alpha_2, \cdots$

where $\iota_1 < \iota_2 < \iota_3$, We call B a partial sequence of A.

EXAMPLES

1.
$$A = 1, \ \frac{1}{2}, \ \frac{1}{3}, \ \frac{1}{4}, \ \frac{1}{5}, \ \cdots$$

$$B = 1, \ \frac{1}{3}, \ \frac{1}{5}, \ \frac{1}{7}, \ \cdots$$

$$C = 1, \ \frac{1}{2^2}, \ \frac{1}{2^3}, \ \frac{1}{2^4}, \ \cdots$$

$$D = 1, \ \frac{1}{2 \cdot 3}, \ \frac{1}{2 \cdot 5}, \ \frac{1}{2 \cdot 7}, \ \cdots$$

Here B, C, D are partial sequences of A.

2.
$$A = 1, \frac{1}{2}, 1, \frac{1}{3}, 1, \frac{1}{4}, \cdots$$

 $B = 1, 1, 1, \cdots$
 $C = \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \cdots$

B and C are partial sequences of A.

103. 1. Among the symbols given in 42, to indicate the limit of a sequence $A = \alpha_1, \alpha_2, \cdots$

one was

$$\lim \alpha_n$$
.

Analogously, we shall denote the limit of a partial sequence

 $B = \alpha_{\iota\iota}, \ \alpha_{\iota\iota}, \ \cdots$

of A, by

$$\lim_{B} \alpha_{n}$$
.

2. We have then, obviously:

If A is regular, so is every partial sequence B; and

$$\lim_{A} \alpha_n = \lim_{B} \alpha_n.$$

3 From this, we conclude at once

The sequence A cannot be regular, if it contains two partial sequences B, C, such that

4 The requence A cannot be regular, if it contains a portial sequence B which is not regular

5 It is sometimes a difficult matter to show that a sequence A is or is not regular. The theorems 3, 4 enable us often to show with ease that A is not regular.

Thus, in Ex 2, 102,

$$\lim_{n \to \infty} a_n = 1$$
, $\lim_{n \to \infty} a_n = 0$.

Hence A is not regular

6 Unless the contrary is stated, it is to be understood that

hm a.

has reference to the whole sequence A

104 1 From 98, we conclude the following theorems, which are often useful

If $\lim_{n\to\infty} (a_n \pm \beta_n) = \sigma$, and $\lim_{n\to\infty} a_n = \sigma$, then $\lim_{n\to\infty} \beta_n$ exists and equals $\pm \sigma \pm a$

2 If $\lim a_n \theta_n = \pi$, and $\lim a_n = a \neq 0$, then $\lim \beta_n$ exists and equals π/a

3 If $\lim \frac{a_n}{B} = \rho$, and $\lim \beta_n = \beta$, then $\lim a_n$ exists and equals $\beta \rho$

4 If $\lim \frac{a_n}{\beta_n} = \rho \neq 0$, and $\lim a_n = a$, then $\lim \beta_n$ exists and equals a/ρ

The demonstration of these theorems we illustrate by proving 1.

We have $\beta_a = \pm (a_a \pm \beta_a) \mp a_a$

Applying 98, 1),

$$\lim \beta_s = \pm \lim (a_s \pm \beta_s) \mp \lim a_s = \pm \sigma \mp a.$$

LIMITS 67

105. 1. Let
$$\lim \alpha_n = \alpha$$
; let β , γ be two numbers, such that $\beta < \alpha < \gamma$.

Then
$$\beta < \alpha_n < \gamma, \qquad n > m.$$

The demonstration is the same as in 48.

2. Let $\lim \alpha_n = \alpha$, and $\alpha_n < \alpha$. Let β be any number $<\alpha$. Then $\beta < \alpha_n < \alpha$. n > m.

106. 1. Let
$$\lim \alpha_n = \alpha$$
; if $\lambda \leq \alpha_n \leq \mu$ for $n > m$; then $\lambda \leq \alpha \leq \mu$.

For, suppose $\alpha > \mu$. Let β be chosen so that

$$\mu < \beta < \alpha$$
.

 $\alpha_n > \mu_n$

Then, by 105, 1,

$$\alpha_n > \beta$$
. $n > m$.

Hence which is a contradiction.

men is a contradiction.

2. *If*

 $\alpha_n \leq \lambda \leq \beta_n$

and if

 $\lim \alpha_n = \lim \beta_n = \mu ;$

then

 $\lambda = \mu$.

For, by 1,

 $\mu \leq \lambda, \ \mu \geqslant \lambda.$

Hence

 $\mu = \lambda$.

$$\alpha_n \leq \beta_n \leq \gamma_n,$$
 (1)

and

 $\lim \alpha_n = \lim \gamma_n = \lambda;$

then

 $\lim \beta_n = \lambda.$

For, subtracting a_n in 1), we get

$$0 \le \beta_n - \alpha_n \le \gamma_n - \alpha_n. \tag{2}$$

Now $\lim (\gamma_n - \alpha_n) = \lim \gamma_n - \lim \alpha_n = \lambda - \lambda = 0.$ (3)

But 3) states that $\epsilon > 0$, m, $\gamma_n - \alpha_n < \epsilon$. n > m

Then, by 2), $\beta_n - \alpha_n < \epsilon$.

This relation states that

$$\lim (\beta_{\bullet} - a_{\bullet}) = 0.$$

As $\lim a_s = \lambda$, we have, by 104, 1,

$$\lim \beta_* = \lambda.$$

108 1 A sequence $A = a_p \, a_p$, whose elements satisfy the relations

is called an increasing sequence

. .

it is a decreasing sequence

If it is either one or the other, but we do not care to specify
which, we may call it a universant sequence

If, on the other hand,

A 15 said to be a monotone increasing sequence

1t 13 a monotone decreasing sequence

If A is either one or the other, but we do not care to specify which, we may call A a monotone sequence

Univariant sequences are special cases of monotone sequences

2 If there exists a fixed positive number G, such that

$$|\alpha| \leq G$$
, $n = 1, 2$

A is said to be limited, otherwise unlimited

109 A limited monotone sequence is regular

For clearness, let $A = a_1 \quad a_2$ be an increasing monotone sequence, and let

$$a_a < G \qquad n = 1, 2, \dots$$
 (1)

(2

To snow that A is regular, we must show that

$$\epsilon > 0$$
, m , $0 \le a_n - a_n < \epsilon$, $n > m$

Since A is monotone increasing,

$$0 \le \alpha_n - \alpha_m$$

To show the rest of 2), take m_0 at pleasure. Either there exists an infinite sequence of indices

$$m_0 < m_1 < m_2 < \cdots \tag{3}$$

such that

$$\alpha_{m_1} - \alpha_{m_0} \equiv \epsilon, \quad \alpha_{m_2} - \alpha_{m_1} \equiv \epsilon, \quad \cdots$$
 (4)

or there does not.

Suppose such a sequence 3) exists. Then, however small ϵ has been taken, we can take the integer p so large that

$$p\epsilon + \alpha_{m_0} > G.$$
 (5)

Adding the first p inequalities 4), we get

$$\alpha_{m_p} - \alpha_{m_0} = p_{\epsilon}$$
.

Hence, by 5),

$$\alpha_{m_p} > G$$
,

which contradicts 1).

We thus conclude that there exist but a finite number of indices m_0 such that 4) holds. Thus we can take m so large that

$$\alpha_n - \alpha_m < \epsilon, \qquad n > m,$$

which proves the other half of 2).

110. 1. A limited increasing sequence of great importance is

$$a_n = \left(1 + \frac{1}{n}\right)^n$$
. $n = 1, 2, \cdots$ (1)

To show that 1) is increasing, i.e. that

$$a_n > a_{n-1}, \tag{2}$$

we employ the relation 94, 5), viz.:

$$\beta^{n} > \alpha^{n-1} \left[\alpha - n(\alpha - \beta) \right]. \tag{3}$$

Set

$$\alpha = 1 + \frac{1}{n-1}, \ \beta = 1 + \frac{1}{n},$$

in 3); we get 2) at once, for $n \ge 2$.

To show that 1) is limited we set

$$\alpha = 1 + \frac{1}{2m} \beta = 1$$
 $n = m + 1$,

in 3) we get

$$1 > \frac{1}{2} \left(1 + \frac{1}{2m}\right)^n$$
 $m = 1, 2$

or squaring

$$4 > \left(1 + \frac{1}{2m}\right)^{2n}$$

Thus

$$a_{2n-1} < a_{2n}$$
 (5

As all positive integers are of the form

$$2m \text{ or } 2m-1$$

 $a.<4 n=1.2.$

2 Since the sequence 1) is limited and monotone, it has a limit by 109. We set

$$e = \lim_{n \to \infty} \left(1 + \frac{1}{n}\right)^n$$
 $n = 1 2 3$

As the reader already knows c = 2.71828 and is the base of the Napierian system of logarithms

111 1 Let $A = a_1$ a_2 , be a regular sequence whose limit is a_1 . In A exist partial monotone sequences B and for each such sequence,

$$\lim \alpha_{q} = \alpha$$

Then are two cases $1^{\circ} \alpha - \alpha_n$ n>m has one sign when not zero $2^{\circ} \alpha - \alpha_n$ may have both signs however large m is taken

Case I To fix the ideas suppose

$$\alpha - \alpha_s \le 0$$
 $n \ge m$ (1)

In this relation, it may happen that for some $m' \ge m$

$$a - a_n = 0$$
 $n \le m$

LIMITS 71

In this case,

$$B = \alpha_m, \ \alpha_{m+1}$$
$$= \alpha_n \ \alpha_n \cdots$$

is a sequence required in the theorem.

Let us suppose now that there are in 1) an infinite number of indices n_s , such that

 $\alpha - \alpha_{n_{\kappa}} > 0$.

Let ν_1 be one of the indices n_{κ} ; then

$$\alpha_{\rm P_s} < \alpha_{\rm s}$$

Let β_1 lie between these, so that

$$\alpha_{r_1} < \beta_1 < \alpha$$
.

Then, by 105, 1, and 103, 2, there are an infinity of elements α_{n_e} , lying between β_1 and α . Let α_{r_e} be one of these, so that

$$\beta_1 < \alpha_{\nu_1} < \alpha$$
.

Let β_2 lie between α_{ν_*} and α_i ; then for some index ν_8 we have

$$\beta_2 < \alpha_{r_*} < \alpha$$
.

In this way we find an increasing sequence

$$B = \alpha_{\nu}, \ \alpha_{\nu}, \ \alpha_{\nu}, \ \cdots$$

which is a partial sequence.

Then, by 103, 2,

$$\lim_{n\to\infty}\alpha_{r_n}=\alpha.$$

The number of sequences B of this type is obviously unlimited.

Case II. Since there are an unlimited number of indices for which

$$\alpha - \alpha_n > 0, \tag{2}$$

let us denote those values of n for which 2) holds, by n_1, n_2, n_3, \cdots . Then the partial sequence of A,

$$A' = \alpha_{n_i}, \ \alpha_{n_i} \cdots$$

belongs to Case I Hence in A' lie an infinity of sequences of the type B

2. The demonstration of 1 shows

If, in the regular sequence $A = a_1, a_2, \ldots$, the a_n do not finally become all equal, there exists in A on infinity of partial univariant sequences B which have all the same limit as A

The Measurement of Rectilinear Seaments Distance

112 In 39, 43, 44, we have made use of the graphical representation of the numbers in R, by points of a right line. We wish now to extend the considerations to numbers in S. With this end in view, we proceed to develop the theory of measurement of rect linear segments and the associated notion of distance.

113 1 Let AB, CD be two rectlinear segments. We say AB is greater than CD, when, if superimposed, AB contains CD as a part, while CD is said to be less than AB If, when superimposed, AB and CD contecde, we say AB and CD are equal

2 We assume, with Archimedes that if the segment AB is laid off a sufficient number of times on the line L, we can obtain a

segment CD' greater than any given segment CD. And conversely, that it is possible to divide a segment CD into a sufficient number

7 7

of equal parts, so that one of them, as \it{CE} , is less than any given segment \it{AB}

114. 1. Let S = AB be a segment we wish to measure; and let U = CD be a segment which we take as a unit of comparison.

If we can divide S into l equal segments, equal to U, i.e. if

$$S = l \cdot U$$

we say l is the measure of S, or l is the length of S.

2. If it is impossible to do this, it may happen that n segments S are equal to m segments U; i.e.

$$n \cdot S = m \cdot U$$
.

We say then, that

$$l=\frac{m}{n}$$

is the measure or length of S.

3. In both cases we say S is commensurable with U.

The segment AB being commensurable, we say its length l expresses the distance of A from B, or B from A. We write

$$l = \text{Dist}(A, B),$$

or more shortly

$$l = A\overline{B}$$
.

115. We show now that the number l, just determined, is unique. This is evident when l is an integer. We suppose, therefore, that

$$nS = mU, (1$$

and

$$n_1 S = m_1 U. (2)$$

Multiplying these equations respectively by n_1 , n, we get

$$nn_1S = n_1mU$$
, $nn_1S = nm_1U$.

$$n_1 m U = n m_1 U$$
.

$$n_1 m = n m_1$$

 \mathbf{r}

$$\frac{m}{n} = \frac{m'}{n'}$$
.

Thus, the two equations 1), 2) lead to the same value of l.

116 1 Let (= m be the measure of S

nS = mU (1

Then

Let us divide U into a equal parts and call V one of them

Then This in 1) gives

+V-II nS = mnV

Hence

SwmP

This shows that by taking a new unit V whose length is 1/n of the old unit, the length of S cao be expressed as an integer

2 The above considerations also give us a new way for defining the length of S In fact, suppose it possible to divide U into a equal parts V, such that S = eV(2

Then For.

l≈".

£3

v = U. hence, multiplying 2) by . we get

 $\epsilon S \approx r \epsilon V \approx r U$.

so that the length I of S is indeed given by 2)

117 Let S = AB T = BC be two segments whose lengths are respectively

 $l = \frac{a}{1}, \quad m = \frac{c}{2},$

a, b, c d being positive integers

If we put them end to end, we get a segment W = AC whose length, we show, is n=l+m

By definition we have

$$bS = aU dT = cU$$

Multiplying these equations respectively by d, b, and adding, we get

$$bd \cdot S + bd \cdot T = ad U + bc U = (ad + bc) U. \tag{1}$$

But

$$bd \cdot S + bd \cdot T = bd \cdot W. \tag{2}$$

Hence 1), 2) give

$$bdW = (ad + bc)U$$
.

Hence

$$n = \frac{ad + bc}{bd} = \frac{a}{b} + \frac{c}{d} = l + m.$$

118. 1. We turn now to the measurement of segments which are incommensurable with the segment chosen as unit. An example of such segments is the diagonal of a square, the side being taken as unit.

To measure AB, we begin by marking off points on the right line L, at a unit distance apart, starting with A. By the axiom of Archimedes, 113, 2, B will fall between two consecutive points of this set, say between A_1 , B_1 .

Let

$$l_1 = \text{Dist}(A, A_1).$$

On the segment A_1B_1 we mark off points at the distance 1/n apart, where n is an arbitrary positive integer.

Then B will fall between two of these points which are consecutive, say between A_2 , B_2 .

Let

$$l_2 = \text{Dist}(A, A_2).$$

We may continue in this way, subdividing each interval A_m , B_m into n equal parts, without end. The point B will never fall on the end point of one of these intervals, for then AB would be commensurable. The sequence of rational numbers

$$l_1, l_2, l_3, \cdots$$
 (1

so determined is monotone increasing, and limited. In fact, all its elements are $< l_1 + 1$. Thus, by 109, the sequence 1) is regu-

lar, and so defines a number λ We say λ is the measure or length of AB, and we write as before

$$\lambda = \text{Dist}(A, B) = \overline{A, B}$$

2. If we had taken the numbers

$$l_{\cdot}' = D_{13}t(A, B_{\cdot}), \quad \kappa = 1, 2, \cdots$$

where B_s denotes the right-hand end of the interval in which B falls, instead of the numbers I_s , we would have got a monotone decreasing limited sequence

whose limit $\lambda' = \lambda$

$$l_{i}^{i}, l_{i}^{i}, l_{i}^{i}, ...$$
 $l_{i}^{i} - l_{i} = \frac{1}{l_{i} + 1},$

whose limit is 0

For.

119 We have defined the length λ of AB by a process which subdivides each interval A, B, into n equal pirts. The question at once arises would this process lead to the same number λ , if

we had divided each interval into m instead of n equal parts?

We prove the following general result. Let us modify the above process so as to divide the first interval into n₁ equal parts, the

second interval into n₂ equal parts, etc. This system of subdivision leads to a sequence which we denote by

$$l_1'$$
 l_2' , l_5' ,

where

$$l_{n'} = \text{Dist}(A, A_{n'})$$

a

The limit of 1) being λ' we show it exists and $\lambda = \lambda'$

For, each point A_n will fall in a certain interval A_n , B_m of the old system of subdivision, where ϵ_n is the lowest index for which this is true

Then $\operatorname{Dist}(AA_m) \gtrsim \operatorname{Dist}(A, A_m^1) \leq \operatorname{Dist}(AB_m)$

But, by 118, 2,

$$\lim \operatorname{Dist}(A, A_{\operatorname{len}}) = \lim \operatorname{Dist}(A, B_{\operatorname{len}}) = \lambda.$$

Hence, by 107,

In Dist $(A, A_{-}') = \lambda$

120. The process explained in 118, 119 is obviously applicable to the case when AB is commensurable. The only difference is that after a certain number of steps the point B may fall on one of the end points of the little segments A_m , B_m . In this case the corresponding sequence

$$l_1, l_2, \cdots l_s, l_s, l_s, \cdots$$

would have all its elements the same after a certain one.

121. We have now two methods for measuring a commensurable segment; viz. those given in 114 and 120.

Let l be the length of AB as given by 114; and λ its length according to 120. We show

$$l = \lambda$$
.

Since AB is, by hypothesis, commensurable, we have, by 117, preserving the notation already employed,

$$l = \text{Dist} (AA_m) + \text{Dist} (A_m B)$$

$$< \text{Dist} (AA_m) + \text{Dist} (A_m B_m). \tag{1}$$

$$\text{Dist} (A_m B_m) = \frac{1}{n^{m-1}},$$

$$0 < l - l_m < \frac{1}{n^{m-1}},$$

$$l_m = \text{Dist} (A, A_m).$$

As

we have, from 1),

where

Passing to the limit, we have, since

$$\lim_{m \to \infty} l_m = \lambda, \lim_{m \to \infty} \frac{1}{n^{m-1}} = 0,$$

$$l = \lambda.$$

122. 1. Let AC, CB be any two segments; we show that

$$Dist(AB) = Dist(AC) + Dist(CB)$$
.

This is a generalization of 117.

We begin by supposing that one of the segments, AC, is commensurable, while the other, CB, is not. Then AB is not commensurable In our process of subdivision, suppose that after the mth step, B falls in the segment B_m B_m . Then A C and CB_m are commensurable Hence, by 117,

$$Dist(AB_{-}) = Dist(AC) + Dist(CB_{-}).$$

In the limit, we get

$$Dist(AB) = Dist(AC) + Dist(CB)$$

2 We pass now to the general case After the mth subdivision,

let $\mathcal C$ fall between $\mathcal C_m$ and $\mathcal C_m'$. Then $A\,\mathcal C_m$ is commensurable Hence, by 1,

$$Dist(AB) = Dist(AC_m) + Dist(C_mB).$$

Passing to the limit, we have

$$Dist(AB) = Dist(AC) + Dist(CB)$$

Correspondence between R and the Points of a Right Line

123 1 On the indefinite right line L mark a point O as origin Let P be any point on L, and let

$$\lambda = \text{Dist}(\theta, P)$$

If P lies to the right of θ we associate with P the number $+\lambda$, if P lies to the left of θ we associate with it $-\lambda$. With the origin we associate the number θ . Thus to any point on D corresponds a number in \Re and to different points correspond different numbers

2 We ask now conversely does there exist for each λ in \Re a point P such that $\{\lambda \mid = \text{Dist}(O, P)^{\frac{\alpha}{2}}\}$

For all rational numbers this is true by wirtue of the axiom of Archimedes, 113, 2

Whether it is true for every number in M. cannot be demonstrated. We therefore service with Dedekind and Cantor that

there shall exist one and only one point P which shall lie to the right of O, if $\lambda > 0$, and to the left of O, if $\lambda < 0$, and such that

$$|\lambda| = \text{Dist}(0, P).$$

This we shall call the Cantor-Dedekind axiom or the axiom of continuity of the right line. As we proceed, it will be made evident that many apparently simple geometric ideas are extremely subtle and complex. One of the most elusive of these is the notion of continuity. To say the right line is continuous because it has no breaks or gaps, is simply to replace one undefined word by another.

- 3. We have now established a one to one correspondence between the numbers of \Re and the points on L. We may consider the points as images or representations of these numbers.
- 124. 1. The correspondence which we have just defined is a generalization of that given in 35 for R. The considerations of 39, 43, 44 can now be extended to \Re without any further comment. The graphical interpretation of sequences and their limits which we thus obtain will illuminate greatly the section on *limits*, 97-111. We recommend the student to go over the demonstrations which we gave there, employing graphical representations as an aid to the reasoning. Indeed, some of the theorems, when interpreted geometrically, seem almost self-evident.
 - 2. Consider, for example, the theorem of 107. We have there three sequences, $A = \{\alpha_n\}$, $B = \{\beta_n\}$, $C = \{\gamma_n\}$. The relation

$$\alpha_n \leq \beta_n \leq \gamma_n$$

states that the point β_n lies in the interval $I_n = (\alpha_n, \gamma_n)$.

Since now both end points of I_n converge to the point λ , evidently any point in I_n , as β_n , must also converge to the point λ .

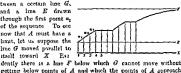

125. As another example, consider the theorem of 109.

To fix the ideas, let $A = \{\alpha_n\}$ be a monotone increasing sequence. The points in the figure represent $\alpha_1, \alpha_2, \cdots$ We have drawn a curve through them, as the eye seizes more easily the law of

increase or decrease of a sequence when such a curve is drawn The reader will observe that since the sequence is monotone, this curve can have segments parallel to the axis X As A is limited.

all the points of A he be tueen a certain line G. and a line E drawn through the first point a, of the sequence To see now that A must have a limit, let us suppose the line & moved parallel to stanl! toward X Est

as an asymptote

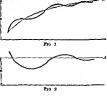

If A is the distance of F from X, evidently

 $\lim \alpha_a = \lambda$.

126 As a final example of the helpfulness of graphical representation, let us consider the theorem of 111

The two cases we considered there are represented in Figs 1 The heavy enryes represent the law of increase and decrease of the sequence A The points a, a,

he on these curves. but are not indicated The straight lines A represent the limit a of The light curve in Fig 1 indicates an

increasing sequence which one could nick out of A By the aid of such a representation the theorem becomes almost

self-evident

127. 1. Let $A = \{\alpha_n\}, B = \{\beta_n\}, C = \{\gamma_n\}.$

Let A be monotone increasing, and C monotone decreasing.

Let

$$\alpha_n \leq \beta_n \leq \gamma_n, \tag{1}$$

and

$$\lim (\gamma_n - \alpha_n) = 0.$$
(2)

Then A, B, C are regular, and have the same limit λ . Also

$$\alpha_n \leq \lambda \leq \gamma_n.$$
 (3)

Graphically, the theorem is obviously true. The points α_n , γ_n determine a set of intervals

$$I_n = (\alpha_n, \gamma_n),$$

such that each I_n lies in the preceding I_{n-1} , and hence in all preceding intervals.

By 2) the lengths of these intervals converge to 0. Geometrically, it is evident that the end points α_n , γ_n of these intervals converge to the same limiting point λ , and that any sequence of points β_n , where β_n is any point in I_n , must also converge to λ .

Arithmetically, the demonstration is as follows:

By hypothesis,

$$\alpha_1 \leq \alpha_2 \leq \alpha_3 \cdots$$

$$\gamma_1 \geq \gamma_2 \geq \gamma_8 \cdots$$
 (4

From 1),

$$\alpha_n \leq \gamma_n$$

Hence, by 4),

$$\alpha_n \leq \gamma_1$$
. $n = 1, 2, \cdots$

Thus A is limited. Similarly, C is limited.

Thus A and C are regular, by 109.

Let

$$\lim \alpha_n = \lambda. \tag{5}$$

Then 2) and 5) give, by 104, 1,

 $\lim \gamma_n = \lambda$.

Then, by 107,

 $\lim \, \beta_n = \lambda.$

2 The preceding theorem may be put in geometrical language, and gives

Let $I_i = (e_n, \gamma_i)$ be a sequence of intervals $n = 1, 2, 3, \dots$ I_i , let $n \mid I_i$ and let the lengths of these intervals converge to I_i the I_i point I_i (including end point). Then the sequence I_i , let I_i regular, and all such sequences have the same limit λ . The point λ let I_i nevery I_i .

3 The reader should avoid the following error

Let ial. if be two sequences, such that

$$hm\left(a_{\bullet} - \beta_{\bullet}\right) = 0 (6$$

Then hm a., hm B. exist and are equal

That this conclusion is false is shown by the following example

$$\alpha_n = (-1)^n + \frac{1}{n}, \ \beta_n = (-1)^n$$

Here neither limit exists, although 6) is satisfied

Dedeland's Partitions

128 We proceed now to establish the notion of partition," introduced by Dedekind to found his theory of irrational numbers.

Let a be any number of \Re , we can use it to throw all numbers of \Re into two classes A, B in A we put all numbers < a. in E all numbers > a The number < we may put in A or B. This division of the numbers of \Re into two classes we call a partition and say a generates a partition (A, B). Geometrically the point s may be used to throw all points of s right line into two classes In class A we put all points to the left of c in B all points to the right of c . The point a we neath neither A of B at believance

Example

Let $a \approx \sqrt{2}$ In A put all numbers $< \sqrt{2}$ in B put the numbers $\leq \sqrt{2}$. This partition may also be generated as follows: In A put all numbers whose square is < 2, in B all numbers whose square is < 2, in B all numbers whose square ≤ 2 .

^{*} The German term is Schuct

- 129. 1. More generally, we shall say that any separation of the numbers of \Re into two classes A, B, such that
 - 1° Any number of A is < any number in B,
- 2° Any number of B is > any number in A, constitutes a partition (A, B).
- 2. The condition 2° is really redundant, as it follows at once from 1°.

In fact, suppose 2° did not follow from 1°; *i.e.* suppose there were a number β in B, \equiv some number α in A. Then there is an α in A which is not < any number in B, for α is not $<\beta$. This is a contradiction.

- 3. Two partitions (A, B) and (C, D) are the same or equal only when A and C contain the same set of numbers; or only when B and D contain the same numbers, excepting possibly the end numbers.
- 130. 1. We consider now this question: suppose a law given which throws all numbers into two classes A, B, such that every number in A is less than any number in B, and every number in B is greater than any number in A. Is there a number λ in \mathfrak{A} which will generate this partition (A, B)? We show there is.

To this end we construct two sequences

$$S = \alpha_1, \quad \alpha_2, \quad \alpha_3, \quad \cdots$$
$$T = \beta_1, \quad \beta_2, \quad \beta_3, \quad \cdots$$

S being monotone increasing, and T monotone decreasing, as follows:

Let α_1 be any number at pleasure in A, and β_1 a number in B. Their arithmetic mean

 $\frac{\alpha_1+\beta_1}{2}$

lies between α_1, β_1 .

If it lies in A, we set

$$\alpha_2 = \frac{1}{2}(\alpha_1 + \beta_1), \ \beta_2 = \beta_1;$$

if it lies in B, we set

$$\alpha_2 = \alpha_1, \ \beta_2 = \frac{1}{2}(\alpha_1 + \beta_1).$$

We build now the arithmetic mean of a_2 , β_2 , and reason with this as before. Continuing this process indefinitely, we get the sequences S and T

By 127, 2, the sequences S, T have a common limit, which we call 1.

Let λ generate the partition (A', B')

We show that

(A B) = (A', B'),

by showing 1° that every number in A' lies in A, and 2° that every number of A lies in A1° Let $a' \neq \lambda$ be any number of A' By 105, 2 there are an

infinity of numbers a_{k} lying between a' and λ But a_{k} is in A_{k} by bypothesis. Hence $a' < a_{k}$ is in A

2° Let a be any number of A We have to show that a $\geqslant \lambda$

Suppose the contrary, $\lambda < a$

Then $\zeta = \alpha - \lambda > 0$

₹≈4-4>

We can take n so great that
$$\beta_n - a_n = \frac{\beta_1 - a_1}{n-1} < \epsilon.$$

a

On the other hand, by supposition,

 $\alpha_{n} < \lambda < \alpha < \beta_{n}$ Hence

 $\beta_n - \alpha_n \ge \alpha - \lambda = \epsilon,$ which contradicts 1)

2 We have thus this theorem

Every partition can be generated by a number in R

131 1 A partition (A, B) cannot be generated by two different numbers A and \(\mu\)

To fix the ideas, let \u2212<

In the partition (C D) generated by μ , C contains all numbers $<\mu$ It therefore continus numbers $>\lambda$, and hence numbers not in A. Hence (A B) (C D) are different

2 Since each number generates one partition and each partition is generated by one number we can establish a uniform or one to

one correspondence between the numbers of \Re and the aggregate of all possible partitions.

In fact, to the number α shall correspond the partition (A, B), that α generates. To the partition (F, G) shall correspond the number λ , which will generate (F, G).

Infinite Limits

- 132. Let $A = a_1, a_2, \cdots$ be an *unlimited* sequence [108, 2]. The following cases may occur:
- 1°. For each positive number G, arbitrarily large, there exists an m, such that $a_n > G$, for every $n \ge m$. In symbols

$$G > 0$$
, m , $\alpha_n > G$, $n \ge m$.

We say the limit of A is plus infinity; and write

$$\lim_{n \to \infty} \alpha_n = +\infty, \quad \lim_{n \to \infty} \alpha_n = +\infty, \quad \alpha_n = +\infty.$$

Such sequences are

ľ

ì

2°. For each negative number G, arbitrarily large, there exists an m, such that $\alpha_n < G$, for every $n \equiv m$. In symbols

$$G < 0$$
, m , $\alpha_n < G$, $n \ge m$.

We say the limit of A is minus infinity; and write

$$\lim_{n\to\infty}\alpha_n=-\infty, \quad \lim \alpha_n=-\infty, \quad \alpha_n$$

Such a sequence is

$$-10, -100, -1000, \cdots$$

In both these cases, we say the limit is definitely or determinately infinite.

3°. The elements α_n do not finally all have one sign, but still $\lim |\alpha_n| = +\infty$.

We say the limit of A is indefinitely or indeterminately infinite. Such a sequence is

1.
$$-2$$
, $+3$, -4 , $+5$, ...

133 1 Case 3 is of hitle importance. We shall therefore in the future, when using the terms the limit is infinite, or certain variables become infinite, always mean definitely infinite, unless the contrary is expressly stated.

The symbol $+\infty$ is frequently written without the + sign. The symbol $\pm\infty$ means that the limit is either $+\infty$ or $-\infty$, and one does not care to specify which

The limits defined in the previous sections are called, in contra

distinction finite limits The symbols $+\infty$, $-\infty$ are not numbers, is they do not lie

in $\mathfrak R$ They are introduced to express shortly certain modes of variation which occur constantly in our reasonings

2 Finally, we wish to state once for all that the terms, the limit exists the limit is \(\lambda\), etc. or an equation as

$$\lim \alpha_n = \lambda,$$

always refer to finite limits unless the supplementary phrase, "finite or infinite is inserted

134 A sequence cannot have both a finite and an infinite limit

For, if $A = \{a_n\}$ has a finite limit, the numbers a_n he between two fixed numbers by 105 1. It is thus limited. It cannot therefore have an infinite limit

135 Let A = [a,] and let B be any partial sequence of A If

$$\lim_{A} \alpha_n = \pm \infty,$$

then

 $\lim_{B}a_{n}=\pm\infty$

The demonstration is obvious

136 If the limit of a sequence $A = \{a_n\}$ is indefinitely infinite its positive and negative terms each form sequences whose limits are respectively $+\infty$ and $-\infty$

For, let $B = \{\beta_n\}$ be the sequence formed of the positive terms of A, and $C = \{\gamma_n\}$ the sequence formed of the negative terms

By hypothesis, G>0, m |a|>G, $n \leq m$

But then, for a sufficiently large m',

$$\beta_n > G$$
, $\gamma_n < -G$, $n \ge m$.

Hence

$$\lim \beta_n = +\infty$$
, $\lim \gamma_n = -\infty$.

137. Let
$$\lim \alpha_n = \alpha$$
, $\lim \beta_n = \pm \infty$;

then 1.
$$\lim (\alpha_n \pm \beta_n) = \pm \infty$$
, $\lim \frac{\alpha_n}{\beta_n} = 0$.

2. If
$$\alpha \neq 0$$
, $\lim \alpha_n \beta_n = \pm \infty$.

3. If
$$\alpha \neq 0$$
, $\frac{\alpha_n}{\beta_n} > 0$, and $\lim \beta_n = 0$;

then

$$\lim \frac{\alpha_n}{\beta_n} = +\infty.$$

The demonstration is obvious.

138. Let
$$\alpha_1$$
, α_2 , α_3 , ... β_1 , β_2 , β_3 , ...

be two sequences.

$$\beta_n \equiv \alpha_n$$
. $n = 1, 2, \cdots$

If $\lim u_n = +\infty$,

then

$$\lim \beta_n = + \infty.$$

For, by hypothesis,

$$G > 0$$
, m , $\alpha_n > G$, $n > m$.

Since

$$\beta_n \equiv \alpha_n$$

we have, a fortiori,

$$\beta_n > G$$
.

Hence

$$\lim \beta_n = +\infty$$
.

139. Let $A = \alpha_1, \ \alpha_2, \ \cdots$ be a monotone increasing sequence. Let

$$B = \alpha_{i_1}, \ \alpha_{i_2}, \ \alpha_{i_3}, \ \cdots \qquad \iota_1 < \iota_2 < \iota_3 \cdots$$

be a partial sequence of A.

If
$$\lim_{\mathcal{B}} \alpha_n = +\infty$$
, then $\lim_{\mathcal{A}} \alpha_n = +\infty$.

For, by hypothesis,

$$G>0$$
, m , a , $>G$ $n>m$.

But since A is monotone increasing,

$$a_r > a_{r_m}$$
 $r > \iota_m$

Hence hes

140 Let m, mm be a sequence of integers whose limit is + \infty Then hm a = 0, of 0 < a < 1. (1

$$=1, \text{ if } \alpha=1. \tag{2}$$

(8

(4

 $=+\infty$, if $\alpha>1$. For. let a>1

We set $a = 1 + \delta$ δ>0.

Then, by 94, 8),

Then, by
$$34, 3)$$
, $\alpha_{\alpha} = (1+\delta)^{m_{\alpha}} > \beta_{\alpha}$, where

 $\beta_* = 1 + m_* \delta$ We apply now 138

Since $\lim \beta_{*} = +\infty$,

we have, from 4), hma =+ x.

 $T_{eft} 0 < \alpha < 1$. We set

Then

$$\rho > 1$$
.

Also

As by 3), $\lim \rho^{m_n} = +\infty$ we have, by 137. $\lim \alpha^{n} = 0$.

which proves 1)

The truth of 2) is obvious.

141. We consider now a few examples involving infinite limits.

Example 1.

$$\alpha_n = 1 + \frac{1}{2} + \frac{1}{3} + \dots + \frac{1}{n}$$
 $n = 1, 2, \dots$

Here

$$\lim \alpha_n = +\infty. \tag{1}$$

For, let

$$\mu = 2^m - 1.$$
 $m = 1, 2, \cdots$

Then

$$\alpha_{\mu} = 1 + \left(\frac{1}{2} + \frac{1}{3}\right) + \left(\frac{1}{4} + \frac{1}{5} + \frac{1}{6} + \frac{1}{7}\right) + \left(\frac{1}{8} + \frac{1}{9} + \dots + \frac{1}{15}\right) + \dots + \left(\frac{1}{2^{m-1}} + \dots + \frac{1}{2^m - 1}\right).$$

Each parenthesis is $> \frac{1}{2}$.

For,

$$\frac{1}{2} + \frac{1}{3} > \frac{1}{4} + \frac{1}{4} = \frac{1}{2},$$

$$\frac{1}{4} + \frac{1}{5} + \frac{1}{6} + \frac{1}{7} > \frac{1}{8} + \frac{1}{8} + \frac{1}{8} + \frac{1}{8} = \frac{1}{2}, \text{ etc.}$$

Thus

$$\alpha_{\mu} > \frac{m}{2}$$

As

$$\lim m = +\infty,$$

we have, by 138,

$$\lim \alpha_{u} = +\infty.$$

But $\{\alpha_{\mu}\}$ is a partial sequence of the increasing sequence $\{\alpha_{n}\}$. Hence, by 139, we have 1).

142. Example 2.

$$\alpha_n = \frac{1}{\alpha} + \frac{1}{\alpha + 1} + \frac{1}{\alpha + 2} + \dots + \frac{1}{\alpha + n}$$

where $\alpha \neq 0, -1, -2, -3, \cdots$

Then

$$\lim \alpha_n = +\infty. \tag{1}$$

Let $\alpha > 0$.

Then there is a positive integer m, such that

$$m-1 \le \alpha < m$$
.

Then
$$\frac{1}{\alpha+p} > \frac{1}{m+p} \qquad p = 0, 1, 2, \dots$$
 Hence
$$a_n > \frac{1}{m} + \frac{1}{m+1} + \dots + \frac{1}{m+1} = \beta_n$$

But, by 135, 141, $\lim \beta_n = +\infty$

Hence, by 138, hm a = + 00

Let a < 0

Then there exists a positive n ger m, such that

0<a+ m<1

Hence
$$\gamma_n = \frac{1}{\alpha + m} + \frac{1}{\alpha + m + 1} + + \frac{1}{\alpha + m + n} > 1 + \frac{1}{2} + \dots + \frac{1}{n}$$

Then, by 141 and 138,

But $\{\gamma_n\}$ is a partial sequence of $\{\alpha_n\}$ Hence we have again 1), by 139

143 Example 3
$$Q_{a} = \frac{\alpha(n+1)}{\beta(\beta+1)} - \frac{(\alpha+n)}{(\beta+n)},$$
where $\beta \neq 0, -1, -2$.

nnere p≠0, -1, -2, 1° a>8.8>0 Let b=a-8

Then

$$\frac{a+m}{\beta+m}=1+\frac{\delta}{\beta+m} \qquad m=0, 1, \cdots n$$

Hence

$$Q_s = \left(1 + \frac{\delta}{\beta}\right)\left(1 + \frac{\delta}{\beta + 1}\right) \left(1 + \frac{\delta}{\beta + n}\right)$$

$$> 1 + \delta\left(\frac{1}{\beta} + \frac{1}{\beta + 1} + \frac{1}{\beta + n}\right).$$

by 90, 1 Hence, by 142,

$$\lim Q_n = +\infty$$
2° $n > \beta$ $\beta < 0$

If a is a negative integer or 0, Q, finally becomes and remains 0

Hence

$$\lim Q_n = 0. \qquad \alpha = 0, -1, -2, \cdots$$

Otherwise, let the positive integer m be taken so large that

$$\beta + m > 0$$
.

Then

$$Q_{n} = \frac{\alpha(\alpha+1)\cdots(\alpha+m-1)}{\beta(\beta+1)\cdots(\beta+m-1)} \cdot \frac{(\alpha+m)\cdots(\alpha+n)}{(\beta+m)\cdots(\beta+n)} = RS_{n}.$$

The first factor R is a constant. In S_n , set

$$\alpha' = \alpha + m$$
, $\beta' = \beta + m$, $n - m = n'$.

Then

$$S_n = \frac{\alpha'(\alpha'+1)\cdots(\alpha'+n')}{\beta'(\beta'+1)\cdots(\beta'+n')}$$

As $\alpha' > \beta' > 0$, S_n falls under ease 1°.

Hence

$$\lim Q_n = \pm \infty,$$

the sign being that of R.

3°. $\alpha < \beta$. If $\alpha = 0, -1, -2, \dots$, evidently $Q_n \doteq 0$.

Let

$$P_n = \frac{\beta(\beta+1)\cdots(\beta+n)}{\alpha(\alpha+1)\cdots(\alpha+n)}.$$

α not zero or a negative integer.

Then P_n falls under cases 1° or 2°.

But

$$Q_n = \frac{1}{P_n}$$

Henee

$$\lim Q_n = 0.$$

4°. $\alpha = \beta \neq 0, -1, -2, \dots$ Here $Q_n = 1$.

Henee

$$\lim Q_n = 1.$$

Different Systems for Expressing Numbers

144. 1. Let a be a positive integer, and m any integer >1. Then we can give a the form

 $a = a_n m^n + a_{n-1} m^{n-1} + \dots + a_0, (1)$

where

$$0 \le a_{\kappa} \le m-1, \qquad \kappa = 0, 1, 2, \cdots$$

and n is a positive integer.

The number m is called the base of the system. The base being given the numbers a_0 , a_1 , a_n completely define the number a and 1) may be written more shortly

 $a = a_{\bullet}a_{\bullet} \quad a_{\bullet}$

When m = 10, we have the decimal system For example, we write $3 \cdot 10^4 + 1 \cdot 10^3 + 7 \cdot 10^4 + 7 \cdot 10 + 9$

more shortly

31779

When m is used as base the numbers a are said to be expressed in an m adic system

2 Let 0 < a < 1 With a measurabled a point on a right line L whose distance from the origin of reference is s To measure this distance let us divide the unit interval into m equal parts, each of these parts into m equal parts, and so on Then, as shown in 18 120.</p>

 $a = \{l_1 \quad l_2 \quad l_3 \quad \}, \tag{2}$

where

$$l_1 = \frac{a_1}{m}$$

$$l_2 = l_1 + \frac{a_2}{m^2} = \frac{a_1}{m} + \frac{a_2}{m^2}, \tag{3}$$

$$l_3 = l_2 + \frac{a_1}{m^2} = \frac{a_1}{m} + \frac{a_2}{m^2} + \frac{a_4}{m^3}$$

The numbers l_1 , l_2 are completely determined when the numbers a_1 , a_2 are given. Thus we is determined when these latter numbers are given, and instead of representing a by the system of equations 2) 3), we may employ the chorter notation

 $a = a_1 a_3 a_3$ For example, let a = 1 and m = 10

Here

$$a_1 = 3$$
, $a_2 = 3$, $a_3 = 3$, \cdots

$$1 = 3333$$

which is the familiar decumal representation of { If we take m = 5, we get the representation

l = 1313131

3. Thus every positive number can be written in the form

$$a_n a_{n-1} \cdots a_0 \cdot b_1 b_2 b_3 \cdots$$

where the a's and b's are ≤ 0 and $\leq m-1$.

4. Certain numbers admit a double representation, in an m-adic system; viz. those numbers in which the b's, after a certain stage, all equal 0 or all equal m-1. In this case we have

$$\alpha = a_n a_{n-1} \cdots a_0 \cdot b_1 b_2 \cdots b_s 0000 \cdots \tag{4}$$

$$\alpha = a_n \cdots n_0 \cdot b_1 \cdots (b_s - 1)(m - 1)(m - 1) \cdots \tag{5}$$

For example, when m = 10,

23.5650000 ...

and

23.5649999 ...

represent the same number. In the future we shall suppose that all such numbers are represented by the form 4), which we shall call the normal form.

5. Numbers of the type

$$a_n a_{n-1} \cdots a_0 \cdot b_1 b_2 \cdots b \quad 000 \cdots$$

all digits after b_r being 0, are usually written more shortly, by omitting these zeros. Such numbers are said to admit a finite representation.

- 145. The expression of a positive number N in normal form in an m-adic system is unique.
 - 1°. Let N be an integer. We show first that

$$m^n > a_0 + a_1 m + \dots + a_{n-1} m^{n-1}$$
 (1)

This is obviously true for n=1. We apply now the method of complete induction. Supposing 1) is true for n=s, we show it is true for n=s+1. Let, then,

$$m^{s} > a_{0} + a_{1}m + \cdots + a_{s-1}m^{s-1}$$
.

Then, since both numbers on the left and right are integers,

$$m^{i} - (a_0 + a_1 m + \dots + a_{i-1} m^{i-1}) \ge 1.$$

 $m^{i+1} - (a_0 + \dots + a_{i-1} m^{i-1}) m \ge m.$

Hence

Subtracting an integer $b = 0, 1, \dots m-1$, from both sides,

$$m^{s+1} - (b + a_0 m + a_1 m^2 + + a_{s-1} m^s) > 0$$
,

Hence, changing the not tion slightly,

$$m^{t+1} > a_0^t + a_1^t m + + a_t m^t,$$
 (2)

if the a' are ≥m-1

This established, let

$$M = a_0 + a_1 m + a_2 m^2 + + a_1 m'$$
,
 $N = b_0 + b_1 m + b_2 m^2 + + b_2 m'$,

where $a, \neq 0, \delta, \neq 0$

Then 1) shows that if $r \ge s$ then $M \ge N$

Hence, it M is to equal A it is necessary that r= :

If r = a, then 1) shows that $M \ge N$, according as $a \ge b$. Thus, if M = N, it is necessary that a, = b. In this way we may continue, and so show that when M = N.

 $a_{r} = b_{r}, \quad a = 0, 1, \dots r$ 2º Let 0 < N < 1

Suppose

$$N = a_1 a_2 \quad a_{r-1} a_r$$

where a, + b. To fix the ideas, let a > b. Then N > P. For.

$$N \ge \left(\frac{a_1}{m} + \frac{a_{r-1}}{m^{r-1}}\right) + \frac{a_r}{m^r} = N_1 + N_2$$

Since P is written in the normal form, there exists an a 57. each that

 $\delta_* < m \sim 1$

Then $P \ge N_1 + \frac{b_r}{mr} + + \frac{b_r + 1}{r} = N_1 + P_2$

But since a.> 5_

$$N_2 > P_1$$

Hence and a fortiori.

$$N_1 + N_2 > N_1 + P_2$$

 $N > P$.

CHAPTER III

EXPONENTIALS AND LOGARITHMS

Rational Exponents

146. Having developed now the number system R with sufficient detail, we shall in this and the subsequent chapters represent numbers in R indifferently by Greek and Latin letters.

147. Up to the present we have defined the symbol

$$a^{\mu}$$
 (1

only for positive integral values of the exponent μ . We proceed to define it for any value of μ , supposing a > 0. We begin with rational values. The numbers 1) are then ealled roots or radicals.

148. 1. Let a > 0, and let n be a positive integer. There exists one and only one positive number satisfying

$$x^n = a. (1$$

Let (B, C) be a partition such that B contains all positive numbers b such that $b^n < a$.

Let ρ be the number which generates (B, C), 130, 2. By 130, 1, we can pick out of B a monotone increasing sequence $\{b_m\}$ and out of C a monotone decreasing sequence $\{c_m\}$ such that

$$\lim b_m = \lim c_m = \rho.$$

As we have, by 106, 2,

$$b_m^n \leq a \leq c_m^n,$$

$$\lim_{m \to \infty} b_m^n = a.$$

As, by 98,
$$\lim b_{n} = \rho^{n},$$

We have

Hence ρ satisfies 1)

There is but one positive solution of 1) For if

we have, from 2), 3),

2 We write

3 When n is odd, 1) has only one solution in \Re , viz, $z = \sqrt[4]{a}$ When n is even, it has two and only two solutions in \Re , viz,

149 1 From the preceding we have readily:

has no solution if n is even and if n is odd, it has one and only one solution i.i.s., $-\sqrt[4]{-a}$

For brevity we often write, when n is odd and a < 0,

When, however, $\alpha > 0$ the radical $\sqrt[4]{\alpha}$ shall always be a positive number

2 The equation $x^*=0$ admits one and only one solution, viz, z=0, in \Re We write

$$\sqrt{0} = 0 = 0$$

150 1 If m, n are positive integers, and a > 0, then

$$(a^n)^m = (a^m)^n$$
 (1)

Set

(2

Then

and

$$\rho^n = a$$
,

$$\rho^m = (a^{\frac{1}{n}})^m;$$

also

$$a^m = \rho^{nm} = (\rho^m)^n. \tag{3}$$

The equation 3) shows that ρ^m is the positive solution of

Hence, by definition, $x^n = a^m$

$$\rho^m = (a^m)^{\frac{1}{n}}. (4)$$

Comparing 2) and 4), we have 1).

2. We write

$$(a^{\frac{1}{n}})^m = (a^m)^{\frac{1}{n}} = a^{\frac{m}{n}}.$$

We have now the definition of

$$a^{\mu}$$
, $a > 0$

for positive rational exponents.

151. Let μ be a positive rational number. We define the symbol $a^{-\mu}$ by the relation

 $a^{-\mu} = \frac{1}{a^{\mu}}.$

We also set

$$a^0 = 1$$
.

152. Let r, s be rational numbers, and a > 0. Then

$$a^r a^s = a^{r+s}. (1$$

This equation expresses the addition theorem for rational exponents. It is a generalization of 74, 2.

To fix the ideas, suppose r, s > 0. Let

$$r=\frac{l}{n}$$
, $s=\frac{m}{n}$

where l, m, n are positive integers.

Let

$$\rho = a^r$$
; then $\rho^n = a^i$.

Let

$$\sigma = a^i$$
; then $\sigma^n = a^m$. (3)

$$(\rho\sigma)^a = a^{l+m}$$

This shows that a or is the positive root of

$$x^n = a^{l+m}$$

Hence

But 2), 3) also give

(4

65

Comparing 4), 5), we get 1) since

$$\frac{l+m}{n} \simeq r+s$$

153 Let u de a rational number, and a > 0 Then M > 0

For let $\mu = \frac{m}{n} > 0$, m, n positive integers.

We have, by 148,

Hence

$$a^2 = a^2$$
 a^2 $a^2 > 0$ m factors

If $\mu < 0$, let $\mu = -\nu, \nu > 0$. Then

$$a^{\mu} = \frac{1}{a^{\nu}}$$

and as $a^a > 0$, so is $a^a > 0$ If $\mu = 0$, we have $a^* = 1$, by 151

154 Let u be a positive fraction and a > 0

a" ≥ 1 according as a ≥ 1

Let
$$\mu = \frac{m}{n}$$
, m , n positive integers

If a > 1, then a' > 1For, suppose the contrary are let

(1

Raising to the nth powers, by 75, 2,

$$a \leq 1$$

which is a contradiction. Hence

If a > 1,

 $a^{\frac{1}{n}} > 1$.

Hence

 $a^{\frac{n}{n}} > 1$, by 75, 2.

The other cases are similarly treated.

155. Let n be a positive integer and a > 0. Then $a^{\frac{1}{n}} \ge a$ according as $a \le 1$.

Let a < 1 and suppose

 $a^{\frac{1}{n}} \geq a$.

Then, by 75, 2,

 $a \ge a^n$.

But when $\alpha < 1$,

 $a^n < a$

by 75, 4. This contradicts 1).

Thus, when a < 1, $a^{\frac{1}{n}} > a$.

The other cases are easily treated now.

156. 1. Let a > 0 and let μ be a positive fraction. If

then

$$a^{\mu} > b > 0,$$

$$a > b^{\frac{1}{\mu}}.$$
(1)

For, let $\mu = \frac{m}{n}$; m, n positive integers.

From

 $a^{\frac{m}{n}} > b$

follows, by 75, 2,

 $a^m > b^m$. (2)

Suppose now 1) were not true, i.e. suppose

 $a \geq b^{\frac{n}{m}}$.

Then

 $a^m \geq b^n$

which contradicts 2,.

(3

a

Let a > 0 and let μ be a negative fraction,

then We can set #=-> >0

Then

This reduces 2 to 1

157 Let
$$\mu < \nu$$
 be too rational numbers let $a > 0$
Then

We can set

Then

$$a^* \le a^*$$
 according as $a \ge 1$
 $\mu = \frac{r}{t}, \nu = \frac{s}{t}$

where r a f are integers and t>0

To fix the ideas, let a>1 and # >>0 Suppose for this case, 1) were not true as that

which is absurd since r < a

Thus 1) is true for this case. In the same way we may treat the other case

158 Let u de a rational number and let a > 0, n = 1, 2,

If hm a. = 1.

then
$$\lim a_s = 1$$
, (1)

To fix the ideas, let

 $a_n < 1$ $a_n < a_n^2 < 1$, 11

if
$$a_n > 1$$
, $1 < a_n < a_n$

by 154, 155 Thus in either case a. hes between 1 and a. Applying 107, we have, using 1),

$$a_n^{\frac{r}{s}} = a_n^{\frac{1}{s}} a_n^{\frac{1}{s}} \cdots a_n^{\frac{s}{s}}, \quad r \text{ factors}$$

ve have, by 98,

$$\lim a_n^{\frac{r}{3}} = \lim a_n^{\mu} = 1.$$

The other cases are now easily treated.

159. Let \(\mu \) be a rational number; let

$$\lim a_n = \alpha > 0, \qquad a_n > 0.$$

Then

$$\lim a_n^{\mu} = \alpha^{\mu}. \tag{1}$$

For,

$$a_n^{\mu} = \alpha^{\mu} \left(\frac{a_n}{\alpha} \right)^{\mu} . \tag{2}$$

But, by hypothesis,

$$\lim_{n \to \infty} \frac{a_n}{n} = 1, \quad \text{by 98.}$$

If we apply now 158 to 2), we get 1).

Irrational Exponents

160. Let $R = r_1, r_2, \cdots$ be a sequence of rational numbers whose limit is 0. Then, if a > 0,

$$\lim a^{r_n}=1. (1$$

We show:

$$\epsilon > 0$$
, m , $|1 - a^{r_n}| < \epsilon$, $n > m$, (2)

which is the same as 1).

Let a > 1, $r_n > 0$; then, by 154,

$$a^{r_n} > 1$$
.

Since $r_n > 0$ and as small as we please, n being sufficiently large, we can take m so large that

$$\frac{1}{r_n} > g, \quad n > m,$$

however large the positive integer g be chosen.

But, by 94, 3),

$$(1+\epsilon)^{\sigma} > 1+g\epsilon$$
.

We can also take q so large that

$$1+g\epsilon > a$$

Then

$$(1+\epsilon)^{s} > a$$
 (3

On the other hand by 157

$$(1+\epsilon)^{\prime *} > (1+\epsilon)^{\prime}$$
 (4

Hence 3) and 4) give

This gives by 156 1)

Hence 2) holds in this case

Let
$$a < 1$$
 $r_* > 0$ We set $a = \frac{1}{2}$.

then

By the preceding case

Hence

$$a^{r_n} = \frac{1}{h^n} > \frac{1}{1+\epsilon} > 1 - \epsilon$$

by 89 1) This gives

Hence 2) holds in this case

Let $r_n < 0$ This case reduces to the case that $r_n > 0$, by observ ing that

$$a^{r_n} = \begin{pmatrix} 1 \\ a \end{pmatrix}^{r_n}$$

We consider now the case that the r. do not all have one sign We divide R into three sequences R. R. R In the first we throw all $r_n = 0$ in the second all $r_n > 0$ in the third all $r_n < 0$ Should any of these sequences contain only a finite number of elements it can be neglected. For we have only to consider a partial sequence of R obtained by omitting the terms of R up to a certain one

Consider R_+ . We have seen there exists in it an index m' such that 2) holds for every n > m'.

Similarly in R_{-} , there exists an index m'' such that 2) holds for every n > m''.

Consider finally R_0 . As $r_n = 0$, 2) holds for every n of R_0 . Thus if m be taken > m', m'', 2) holds for every n > m in R.

161. Let $A = a_1, a_2, \cdots$ be a regular sequence of rational numbers, and let b > 0. Then

$$b^{a_1}, b^{a_2}, \cdots$$
 (1

is regular.

We have to show:

$$\epsilon > 0, m, |b^{\alpha_n} - b^{\alpha_m}| < \epsilon, n > m.$$
 (2)

Set

$$d_n = b^{a_n} - b^{a_m} = b^{a_m} (b^{a_n - a_m} - 1).$$
 (3)

Since A is regular, we have

$$\delta > 0$$
, m , $|a_n - a_m| < \delta$. $n > m$.

But if δ is taken small enough, by 160,

$$|b^{a_n-a_m}-1|<\eta, \tag{4}$$

where $\eta > 0$ is arbitrarily small.

Since A is regular, there exist, by 65, 5, two rational numbers, Q, R, such that

$$Q < a_n < R.$$
 $n = 1, 2, ...$ (5)

Then 3) gives, by 4) and 5),

$$|d_n| < b^R \eta$$
, if $b > 1$;
 $< b^Q \eta$, if $b < 1$, by 157.

If b>1, we take

$$\eta = \frac{\epsilon}{h^R};$$

if
$$b < 1$$
, we take

$$\eta = \frac{\epsilon}{1.0}$$

Then in either case 2) holds.

The case that b=1 requires no demonstration.

162 Let a1 s2 and a1 a2 be two sequences of rational numbers having the same limit. Then if b>0,

$$\lim b^{-} = \lim b^{-}$$
 (1

€8

(1

By 161, both limits in 1) exist

Let
$$d_a = b^{a_a} - b^{a_a} = b^{a_a}(1 - b^{a_a - a_a})$$
 (2)

We have only to show that

$$\lim d_{\mathbf{a}} = 0$$
 But

 $\lim (a_n - a_n) = 0$

Hence 2) 4) give 3)

163 We are now in the position to define irrational exponents Let

$$\mu \approx (r_1 \ r_2 \)$$

be a representation of
$$\mu$$
 We say

By 161, the limit on the right of 1) exists, by 162, it is the same whatever representation of μ is taken

164 1 Let r_1 r_2 be a sequence of rational numbers having a rational limit r . Then, if b>0

 $\lim b^{r_a} = b^r$ In fact the sequence

$$r'_1 r'_2 r'_2$$
 , $r'_n = r$ $n = 1, 2,$

has r as limit

By 162
$$\lim b^* = \lim b^*$$
 (2)

 $\lim b^* = \lim b^* = b^*$ This in 2) gives 1)

2 The object of 1 is to show that the definition of σ^* given in 163 does not conflict with that given in 150, 151, in case μ is rational

165. 1. Let μ be an arbitrary number, and r, s, two rational numbers, such that $r < \mu < s$. Then for b > 0,

$$b^r \geqslant b^{\mu} \geqslant b^s$$
, according as $b \leqslant 1$. (1)

For, let

15 -

$$\mu=(m_1,\,m_2,\,\cdots),$$

the m's being rational.

Then, by 105, 1,

$$r < m_n < s$$
. $n > \nu$.

Hence, by 157,

$$b^r < b^{m_n} < b^r$$
, if $b > 1$.

Then passing to the limit, by 106, 1,

$$b' \leq b^{\mu} \leq b^{\mathfrak{z}}. \tag{2}$$

Here the equality sign must be suppressed. For, let r' be another rational number such that

 $r < r' < \mu$.

Then, as in 2),

$$b^r \le b^{\mu}. \tag{3}$$

But

$$b^r < b^{r'}, (4$$

by 157. From 3), 4) we have

$$b^r < b^u$$
.

Thus the equality sign in 2) must be suppressed.

The truth of 1), when b < 1, follows in a similar manner.

2. As a corollary of 1, we have:

Let a > 0; then a^{μ} vanishes for no value of μ .

In fact, the relation 1 shows that a^{μ} always lies between two positive numbers, by 153.

166. 1. The properties given in the preceding articles for rational exponents hold for irrational exponents also. We illustrate the demonstration in a few cases.

Let $\lambda < \mu$, and b > 0. Then

$$b^{\lambda} \leq b^{\mu}$$
, according as $b \geq 1$ (1)

To fix the ideas, suppose \$>1 Let r be a rational number, such that **λ<r<**μ

Beck. 2 As corollary we have

If b > 1, we conclude from

whereas, if 0 < b < 1, we conclude that

3 In 1) let \ = 0 Since *b*° = 1

we bave

Let
$$\mu > 0$$
, and $\delta > 0$, then

$$\delta' \gtrless 1$$
, according as $\delta \gtrless 1$

167
$$b = \frac{1}{k_0}$$
 $b > 0$

For, let $\alpha = (a_1 a_2)$

$$-a = (-a_1 - a_2)$$
, by 71, 8.

Since, by 151.

$$b = \frac{1}{b^{n_1}}$$

we have

Chen

$$b^{-a} = \lim b^{-a} = \frac{1}{\lim b^{a}} = \frac{1}{b^{a}}$$

since 8° ≠ 0, by 165, 2

168. If
$$a > 0$$
,

$$a^{\lambda}a^{\mu} = a^{\lambda+\mu}$$
.

This is the addition theorem for any exponents, and is a generalization of 152.

Let

 $\lambda = \lim_{n \to \infty} \lambda_n, \ \mu = \lim_{n \to \infty} \mu_n.$

Then

 $a^{\lambda} = \lim a^{\lambda_n}, \ a^{\mu} = \lim a^{\mu_n}.$

Hence

$$a^{\lambda}a^{\mu} = \lim a^{\lambda_n} \lim a^{\mu_n} = \lim a^{\lambda_n}a^{\mu_n}$$

= $\lim a^{\lambda_n + \mu_n}$, by 152,
= $a^{\lambda + \mu}$.

169. Let $\lambda_1, \lambda_2, \dots$ be a sequence whose limit is $+\infty$.

If $\alpha > 0$,

$$\lim a^{\lambda_n} = \begin{cases} +\infty, & \text{if } a > 1, \\ 0, & \text{if } a < 1. \end{cases}$$

For, let a > 1.

Let l_n be the greatest integer in λ_n .

Since

$$\lim \lambda_n = + \infty, \qquad \lim l_n = + \infty.$$

Then, by 140,

$$\lim a^{l_n} = + \infty.$$

As

$$a^{\lambda_n} \subseteq a^{l_n}$$

$$\lim a^{\lambda_n} = + \infty,$$

by 138.

Let a < 1.

Set

$$b = \frac{1}{a}$$
. Then $b > 1$.

The demonstration follows now at once.

170. Let a_1, a_2, \dots be a sequence of positive numbers whose limit is 1.

Then

$$\lim a_n{}^{\lambda}=1.$$

Let r. a be rational numbers, such that

Then, by 166, 1,

$$a_n \leq a_n \leq a_n$$
, $a_n \geq 1$;

(1

(2

(2

 $a_n < a_n < a_n < 1$

Let us apply now 107 Since, by 158.

 $\lim a_n' = \lim a_n' = 1,$ we have, from 1), 2),

lim a. *= 1 .

171 Let a, a be a sequence of positive numbers whose limit ua>0 Then hm a, 2 = a1 0

For. $a_n^{\lambda} = \alpha^{\lambda} \left(\frac{a_n}{a}\right)^{\lambda}$

Since, by 170, $\lim \frac{a_n}{n} = 1,$

1) follows from 2) at once

172 Let A. A. be a sequence whose limit is h. If a > 0,

hm a** = a* (1

Fat. let 7 7 7 7 1 8 8 8 7

be two sequences of rational numbers whose limits are & and such that

 $r_a < \lambda_a < s_a$, n = 1, 2.

To fix the ideas, let a > 1, then, by 166.

 $a^n < a^n < a^n$ By 162,

lum of a = lum of

The application of 107 to 2) gives 1) The case that a \$\mathre{2}\$ 1 is now readily treated

Logarithms

173. Let a, b > 0, and $b \neq 1$. The equation

$$b^x = a \tag{1}$$

has one, and only one, solution.

To fix the ideas, let b>1. We form a partition (C, D) in which C contains all numbers c, such that

$$b^c \leq \alpha$$
;

while D contains all numbers d, such that

$$b^d > a$$
.

This separation of the numbers of \Re into the classes C, D is indeed a partition. For every number of C is < any number of D.

In fact, from

$$b^c < b^d$$

follows, by 166, 2,

$$c < d$$
.

Let ξ be the number which generates (C, D); let

$$c_1\!\le\!c_2\!\le\cdots$$

$$d_1 \ge d_2 \ge \cdots$$

be the monotone sequences of 130, whose common limit is ξ .

Then $b^{\xi} = a$. (2)

For, by 171,
$$\lim b^{c_n} = \lim b^{d_n} = b^{\xi}$$
. (3)

On the other hand,
$$b^{c_n} < \alpha < b^{d_n}$$
. (4)

From 3), 4) we have, by 106, 2,

$$\lim b^{c_n} = a. ag{5}$$

From 3), 5) we have 2).

The equation 2) shows that ξ is a solution 1). Let η be also a solution, so that

$$b^{\eta}=a. ag{6}$$

From 2), 6) we have

$$b^{\xi} = b^{\eta}$$
.

Hence, from 166, 2,

$$\xi = \eta$$
.

174 1 As we have just seen the equation

$$b^{z} = a$$
, $a > 0$ $b > 0$ and $\neq 1$,

admits one and only one solution. This uniquely determined number \$\xi\$ we call the logarithm of a the base being b and write

$$\dot{\mathbf{f}} = \log_{\mathbf{a}} a$$

or when we do not care to indicate the base,

$$\xi = \log a$$

2 Wr shall suppose once for all that the base b is ≠1 also that the numbers whose logarithms we are considering are >0

3 From

$$\log u = \log v$$

follows

The demonstration is obvious

175

$$\log ab = \log a + \log b$$

This is the addition theorem of logarithms. Let the base be a lf

then

$$c^a = a \quad c^a = b$$

Multiplying we have From the equation

$$c^{a}c^{a} = c^{a} \stackrel{\beta}{=} ab$$

$$c^{a+\beta} = ab$$

we have

$$\log ab = a + \beta = \log a + \log b$$

176 By using the properties of exponentials we may deduce in a similar manner all the ordinary properties of logarithms. As this presents nothing of interest, we pass on. We note however the following important relation

Let a>0 and b be the base of our logarithms Then

$$a^n = b^{n \log a}$$

(2

(1

(2

For, by definition, $h^{\log a^{\mu}} = a^{\mu}$ $\log a^{\mu} = \mu \log a.$ But

This in 2) gives 1).

177. Let a_1, a_2, \cdots be a sequence whose limit is 1. Then $\lim \log a_n = 0.$

To fix the ideas, let b, the base of our logarithms, be > 1.

Let $\epsilon > 0$, then, by 166, 3,

Hence $\delta = 1 - \frac{1}{L} > 0.$ (3

Since $\lim a_n = 1$

 $\delta > 0$, m, $-\delta < a_n - 1 < \delta$, n > m; we have

(4 which gives $1-\delta < a_n < 1+\delta$.

From 3) we have $1-\delta=\frac{1}{k}$

This in 4) gives (5

 $a_n > \frac{1}{h\epsilon}$ On the other hand,

 $\delta = \frac{b^{\epsilon} - 1}{b^{\epsilon}} < b^{\epsilon} - 1,$

by 3), 2). (6 This gives $1 + \delta < b^{\epsilon}$.

Then 6) and 4) give (7

 $a_{-} < b^{\epsilon}$.

From 5), 7) we have finally

 $b^{-\epsilon} < a_n < b^{\epsilon}$.

This may be written, by 176, 1),

 $b^{-\epsilon} < b^{\log a_n} < b^{\epsilon}$.

Hence, by 166, 2, $-\epsilon < \log a_n < \epsilon, \quad n > m,$

which is another form of 1).

178 Let
$$\lim a_n = a > 0$$
 Then

$$\lim \log a_n = \log a \qquad a_n > 0$$

 $\lim \log a_n = \log a_n$

$$a = a \stackrel{d}{=}$$

log
$$a_n = \log a + \log \frac{a_n}{a}$$
As
$$\lim \frac{a_n}{a} = 1$$

179 Let a.a. be a sequence whose limit is + 00

$$\lim \log_b a_a = \begin{cases} +\infty & \text{if } b > 1 \\ 0 & \text{if } b < 1 \end{cases}$$

Let b>1 Let m, be an integer such that

aince

The case that b < 1 follows at once now

Some Theorems on Lamits

lim lor a. m + m

 $b^{\alpha_s} \leq a_s \leq b^{-s+1}$

 $\log a_a > m_a$

lm # = + 00.

hm a. = + m

180 Let $A=a_1$ a_2 , be any sequence such however that its limit is $\pm\infty$ when it is not limited let $B=b_1$ b_2 , be an increasing sequence whose limit is $+\infty$ If

$$l = \lim \frac{a_{s+1} - a_s}{b_{s+1} - b_s}$$

$$\lim_{l \to \infty} \frac{d_s}{l} = l$$

(1

(2

a

a

Then

Proof. 1°. I finite.

Set

$$q_n = \frac{a_{n+1} - a_n}{b_{n+1} - b_n}, \quad q_{n,p} = \frac{a_{n+p} - a_n}{b_{n+p} - b_n}.$$

From 1) we have:

Hence

$$\delta > 0$$
, m , $|l - q_n| < \delta$, $n \ge m$.
 $l - \delta < q_m < l + \delta$,
 $l - \delta < q_{m+1} < l + \delta$,
 \vdots
 $l - \delta < q_{m+p-1} < l + \delta$.

To these inequalities apply 93, setting the y's equal 1. Then

$$l-\delta < q_{m,p} < l+\delta$$

or

$$q_{m,p} - \delta < l < q_{m,p} + \delta.$$

$$\lim_{m \to \infty} q_{m,p} = 0,$$
(3)

If A is limited;

since, by hypothesis, $b_n \doteq +\infty$.

In 3, pass to the limit $p = \infty$; we get

$$-\delta \leq l \leq \delta$$
.

Hence

$$l=0.$$

But on the supposition that A is limited,

$$\lim \frac{a_n}{b_n} = 0.$$

Thus 2) holds in this case.

If A is not limited;

 $\delta > 0$ being small at pleasure, and m fixed, we have, by 92,

$$\delta > 0, \quad p_0, \quad \frac{1 - \frac{b_m}{b_{m+p}}}{1 - \frac{a_m}{a_{m+p}}} = 1 + \delta_1; \quad |\delta_1| < \delta, \quad p > p_0.$$
 (4)

(5

(6

 α

Now

$$q_{n,p} = \frac{a_{n+p} \left(1 - \frac{a_n}{a_{n+p}}\right)}{b_{n+p} \left(1 - \frac{b_n}{b_{n+p}}\right)}$$

Also, by 3),

$$q_{n,p} = l + \delta' \qquad |\delta'| < \delta$$

From 5) we get, using 4), 6),

$$\frac{a_{n+s}}{b_{n+s}} = (l+\delta)(1+\delta_1)$$

Hence

$$= 1 + l\delta_1 + \delta_1 + \delta_2 \delta',$$

$$\frac{\sigma_{A+P}}{\delta_{A+P}} - l = l\delta_1 + \delta' + \delta_2 \delta',$$

and

$$\left| l - \frac{a_{m+p}}{b_{m+p}} \right| < \delta(|l| + 1 + \delta)$$

$$< \delta(|l| + 2),$$

-

supposing δ<1
If now we take

a > 0, $m \neq a > a = n > m$

7) gives 2)

2° l infinite To fix the ideas, suppose $l = +\infty$.

Then

Applying 93, we get

This shows that $q_{a,p} > g \qquad p = 1 \quad 2,$ $\lim a_n = +\infty$

Then 5) shows that, taking η such that $0 < \eta < 1$.

$$q_{m,p} = \frac{a_{m+p}}{b_{m+p}} (1 + \eta^t), |\eta^t| < \eta p > p_0$$

by 92 Hence

$$\frac{a_{n+p}}{\delta_{n+p}} = \frac{q_{n,p}}{1+\eta'} > \frac{q}{1+\eta}$$

If we take

$$g>(1+\eta)G$$

where $m{G}$ is arbitrarily large, we have

$$\frac{a_n}{b_n} > G$$
. $n > m + p$.

This proves 2) for this case.

181. Let a_1, a_2, \cdots be a sequence whose limit, finite or infinite, is

Then

$$\lim \frac{a_1 + a_2 + \dots + a_n}{n} = \alpha.$$

Let

$$A_n = a_1 + \dots + a_n.$$

Then

$$a_n = \frac{A_n - A_{n-1}}{n - (n-1)}.$$

Hence, by 180,

$$\lim \frac{A_n}{n} = \alpha.$$

182. Let a_1, a_2, \dots be a sequence whose terms are positive, and whose limit, finite or infinite, is $\alpha > 0$.

Then

$$\lim \sqrt[n]{a_1 a_2 \cdots a_n} = \alpha. \tag{1}$$

1°. a finite. Consider the auxiliary sequence

$$\log a_1$$
, $\log a_2$, ...; base > 1.

By 178,

$$\lim \log a_n = \log \alpha. \tag{2}$$

By 181 and 2),

$$\lim_{n \to \infty} \frac{1}{n} (\log a_1 + \dots + \log a_n) = \log \alpha.$$
 (3)

But

$$\frac{1}{n}(\log a_1 + \dots + \log a_n) = \log \sqrt[n]{a_1 a_2 \cdots a_n}.$$
 (4)

From 3), 4) we have 1).

2°. a infinite. To fix the ideas, let $\alpha = +\infty$.

By 179,

 $\lim \log a_n = +\infty.$

116 By 181,

 $\lim \log \sqrt{a_1 a_2} \quad a_n = \alpha = +\infty$

Thus

 $\lim \sqrt[4]{a_1} \quad a_2 = +\infty.$

Hence 1) is true in this case

183 Let an an be a sequence of positive numbers

Let

 $\lim \frac{a_n}{a} = a \neq 0$, finite or infinite

Then

$$\lim \sqrt[n]{a_n} = a$$

For,

$$\sqrt[n]{a_n} = \sqrt[n]{\frac{a_n}{a_{n-1}}} \frac{a_{n-1}}{a_{n-2}} \frac{a_2}{a_1} a_1$$

Apply now 182

184 Let a_1 a_2 , be a sequence whose limit is 0. Let b_1 b_3 , be a decreasing sequence whose limit is 0. Let

 $\lim_{h \to 0} \frac{a_n - a_{n-1}}{h} = l, \text{ finite or infinite}$

Then

$$\lim_{k \to 1} \frac{a_*}{k} = l \tag{1}$$

1º I finite As in 180, we have

$$\epsilon > 0$$
, $m' \left| \frac{a_m - a_{m+p}}{\lambda} - \ell \right| < \epsilon$, $p = 1, 2, \dots m > m'$.

Since by 92,

$$\lim_{p \to \infty} \frac{a_m - a_{m+p}}{b - b} = \frac{a_m}{b},$$

we have

$$\epsilon$$
, p_0 , $\left|\frac{a_m - a_{m+p} - a_m}{b - b}\right| < \frac{\epsilon}{3}$, $p > p_0$ (3)

Adding 2), 3), we get

$$\left|\frac{a_m}{\delta} - l\right| < \epsilon, \quad m > m'$$

2°. l infinite. Let $l = +\infty$.

Then

$$G > 0$$
, m' , $q_{m,p} = \frac{a_m - a_{m+p}}{b_m - b_{m+p}} > G$; $p = 1, 2, \dots m > m'$.

But for sufficiently large p,

$$q_{m,p} = \frac{a_m}{b_m} + \delta_1; |\delta_1| < \delta, \text{ by } 92.$$

Hence

$$\frac{a_m}{b_m} > G - \delta = g.$$

Hence

$$\frac{a_m}{b_m} > g \; ; \qquad m > m'.$$

and g is large at pleasure, since G is.

185. EXAMPLES $\lim_{n\to\infty}\frac{\log n}{n}=0.$ 1. For, $\frac{\log n - \log (n-1)}{n - (n-1)} = \log \frac{n}{n-1} = 0.$ $\lim_{n \to \infty} \frac{e^n}{n} = +\infty.$ 2. For. $\frac{e^n - e^{n-1}}{n - (n-1)} = e^n \left(1 - \frac{1}{e}\right) \doteq + \infty.$ $\lim_{n\to\infty}\sqrt[n]{n}=1.$ 3. For, $\frac{n}{n} \doteq 1$. $\lim_{n\to\infty} \sqrt[n]{n} = +\infty.$ 4. For, $\frac{n!}{n!} = n \doteq +\infty.$

CHAPTER IV

THE ELEMENTARY FUNCTIONS NOTION OF A FUNCTION IN GENERAL

PUNCTIONS OF OME VARIABLE

Definitions

186 The functions of elementary mathematics are the following

Integral rational functions Rational functions Algebraic functions Circular functions Exponential functions Inverse circular functions Logarithmic functions

The reader is already familiar with the simpler properties of these functions, which we may call the elementary functions. We wish, however, to restate some of them for the sake of clearness

187 In applied mathematics we deal with a great variety of quantities, as length, are, mass time, energy, electromotive force, entropy, etc. In a given problem some of these quantities vary, others are fixed or constant.

The measures of these quantities are numbers

In certain parts of pure mathematics we study the relations between certain sets of numbers without reference to any physical or geometrical quantities their may mensure. In either case we find it convenient to employ certain letters or symbols to which we assign one or more numbers, or as we say, numerical values.

A symbol which has only one value in a given problem is a constant

A symbol which takes on more than one value, in general an infinity of values, is a variable 188. The set of values a variable takes on is called the domain of the variable.

It is often convenient to represent the values of a variable by points on a right line called the axis of the variable, as explained in 123. The domain of a variable may embrace all the numbers in \Re , or, as is more often the case, only a part of these numbers. Very frequently the domain is, speaking geometrically, an interval; *i.e.* the variable x takes on all values satisfying the relation

$$a < x < b$$
.

Such an interval we shall represent by the symbol

Frequently one or both the end points a, b are excluded. Then we use the symbols

$$(a^*, b)$$
 for $a < x \le b$;
 (a, b^*) for $a \le x < b$;
 (a^*, b^*) for $a < x < b$.

Similarly,

$$(a, +\infty)$$
 includes all $x \ge a$;
 $(-\infty, a)$ includes all $x \ge a$;
 $(-\infty, +\infty)$ includes all x in \Re .

A point of the interval (a, b) which is not an end point is within the interval.

189. Let x be a variable, whose domain call D. Let a law be given which assigns for each value of x in D one or more values to y. We say y is a function of x, and write

$$y = f(x)$$
, or $y = \phi(x)$, etc.

If y has only one value assigned to it for each value of x in D, we say y is a one-valued function, otherwise y is many-valued. The variable x is called the independent variable or argument; y is called the dependent variable

We must note, however, that y may be a constant

The domain of the independent variable x which enters in the law defining a function f(x) is also called the domain of definition of the function

The those very general definition of a function is due to Dirichlet

190 The reader is already familiar with the graphical representation of a function, by the aid of two rectangular axes

Lat

y = f(x)

be a given function whose domain of definition call D

The graphical representation of D is a set of points on the x 1219 Let a be a value of a to which corresponds

the value b of y The point P in the figure whose coordinates are a b represents the value of the function for x = a

As x runs over the values of its domain D, the point P runs over a set of points, which we call the graph of f(z)

191 1 Another representation of a function is the following We take two axes as in the figure, one for x one for y In this representation, the graph of f(x) is a set of points on the waxis

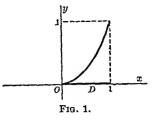

2 The reider will observe this important difference between the two modes of representation just given. In the first we know for each point P of the graph the corresponding values of both x and y In the second mode of representation, we do not know in general the value of x corresponding to a point P of the graph, and conversely In spite of this deficiency, we shall find that this second representation is extremely useful especially the case when we come to consider functions of a variables

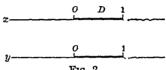

192. Ex. 1. Let *D* be given by
$$0 < x < 1$$
:

while y is given by

$$y=x^2$$
.

The graph of y in the first mode of representation is the arc of the parabola given in Fig. 1. The domain of definition D is the segment (0, 1) on the x-axis, drawn heavy in the figure.

In the second mode of representation the graph of y is the segment marked heavy on the y-axis (Fig. 2).

193. Ex. 2. As in Ex. 1, let

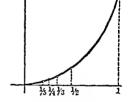

$$y=x^2$$
.

Let, however, the domain of definition D embrace only the values of $x = 1, \frac{1}{5}, \frac{1}{5}, \frac{1}{3}, \cdots$

In the first representation the graph of y is a set of points lying on the arc of the parabola of Ex. 1.

In the second representation it is the set of points $1, \frac{1}{4}, \frac{1}{6}, \frac{1}{16}, \dots$

on the y-axis.

In both modes of representation, the representation of D is the set of points $1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{1}{5}, \cdots$

on the x-axis.

Integral Rational Functions

194. These functions are of the type

$$y = a_0 + a_1 x + a_2 x^2 + \dots + a_m x^m, \tag{1}$$

where the a's are constants, and m is a positive integer or 0.

Such functions are called polynomials in algebra The number m is called the degree of the polynomial y When m=1, we have

$$y = a_4 + a_1 x \tag{2}$$

The graph of 2) is a straight line for this reason an integral rational function of the first degree is called linear

When m=0 or when $\sigma_{*}=0$ in 2) we have

$$y = a_0$$
 a constant (3

We still say y is a function of x In fact 3) states that for each value of x the corresponding value of y is as

The graph of 3) is a line parallel to the z axis. Since the equation 1) sasigns to wa value for each value of x the domain of de mition of y embraces all numbers of R Speaking geometrically as we often shall in the future it includes all the points of the # 4X15

bince 1) assigns only one value to y for each value of x y is a or e valued function

195 In algebra we learn that if a polynomial

$$P_m = a_0 + a_1 x + a_m x^m \tag{1}$$

vanishes for x = a, we can write

$$P = (x - \alpha)P_{\alpha - 1}$$

where P_{m-1} is a polynomial of degree m-1 We learn also in algebra that a polynomial of degree m cannot vanish more than m times without being identically 0 in which case all the coefficients in 1) are 0

Should 1) vanish for

$$x = \alpha_1 \ \alpha_2 \ \alpha_n$$
 (2)

we have

$$P_m \simeq a_m(x-a_1)(x-a_2)$$
 $(x-a_m)$

The numbers 2) are called roots or zeros of P.

Rational Functions

196. The quotient of two integral rational functions of x is called a rational function.

Their general type is given by

$$y = \frac{a_0 + a_1 x + \dots + a_n x^n}{b_0 + b_1 x + \dots + b_n x^n},$$
 (1)

where the a's and b's are constants and m, n are positive integers or 0.

The expression 1) involves division by zero for those values of x for which the denominator vanishes. The domain of definition D of a rational function includes therefore all points on the x-axis except the zeros of the denominator. These zeros we shall call the poles of y. Since 1) assigns only one value to y for each point of D, a rational function of x is one-valued.

The degree of y is the greater of the two integers m, n; supposing, of course, that $a_n, b_n \neq 0$.

When y is of the first degree, it is called linear. The type of a linear rational function is, therefore,

$$y = \frac{a_0 + a_1 x}{b_0 + b_1 x}.$$

The rational function includes the integral rational function as a special case.

In fact, let the numerator be divisible by the denominator, then 1) reduces to a polynomial. This takes place in particular when the denominator reduces to a constant.

Algebraic Functions

197. We say y is an algebraic function of x when it satisfies an equation of the type

$$y^{n} + R_{1}y^{n-1} + R_{n}y^{n-2} + \dots + R_{n-1}y + R_{n} = 0,$$
(1)

where n is a positive integer, and the R's are rational functions of x.

The degree of y is n.

Let us give to x a definite value x=a If a is a pole of any of the Rs, the equation 1) has no meaning for this point, and it does not lie in the domain of definition of y

Suppose a is not a pole of any of the Rs

Then each R_m takes on a constant value, say A_m and 1) goes over into $y^n + A_1 y^{n-1} + \dots + A_n y + A_n = 0$, (2)

Equation 2) may have no real roots In this case a does not belong to the domain of definition of y. On the other hand, 2) cannot have more this u real roots for x=a

These considerations show that y is at most an n vilued function whose domain of definition embraces all or only a part of the paxis

If we clear of fractions in 1), we may write it

$$P_0 y^n + P_1 y^{n-1} + P_{n-1} y + P_n = 0$$

where now the coefficients of y are polynomials in # Evidently either 1) or 3) may be used as definition of an algebraic function

198 The algebraic functions include the rational functions as a special case

For, if n=1, the equation 1) of 197 takes on the form

$$y + R_1 = 0$$
,
 $y = \sim R$.

But - Rt is any retional function

199 An expression which can be formed from x and certain constants by the four rational operations and the extraction of roots, each repeated a finite number of times, is called an explicit absolute function

Such a function is

20

$$y = a - \frac{b}{x^2} + \sqrt[3]{\frac{a + bx^5}{A + \sqrt{1 + \sqrt{x^2}}}} + \sqrt[4]{\frac{1}{1 - x^2} + \sqrt{a + bx}}$$
 (1)

Obviously 1) can be obtained from

by the aid of the five operations, addition, subtraction, multiplica tion, division, and the extraction of roots, each repeated only a finite number of times.

It is known that every explicit algebraic function y satisfies an equation of the type 197, 1). Hence every explicit algebraic function is an algebraic function, by 197.

The converse is, however, not true; every algebraic function y cannot be brought into the form of an explicit algebraic function.

This is due to the fact that equations of degree n > 4 cannot, in general, be solved by the extraction of roots, or, as we say, do not admit of an algebraic solution.

200. All functions which are not algebraic functions are called transcendental functions.

The terms algebraic and transcendental may also be applied to the numbers of M.

Any number a which satisfies an equation of the type

$$x^{n} + a_{1}x^{n-1} + a_{2}x^{n-2} + \dots + a_{n-1}x + a_{n} = 0,$$
 (1)

where n is a positive integer, and the a's are rational numbers, is called an algebraic number. All other numbers of R are transcendental numbers.

When n=1, the equation 1) defines a rational number; the rational numbers are special cases of algebraic numbers.

Circular Functions

201. As the reader already knows, the circular functions may be defined as the lengths of certain lines connected with a circle of unit radius.

Thus, in the figure

$$\sin x = CE$$
, $\cos x = OE$, $\tan x = AB$,

etc. We have shown in Chapter II how the reofilinear segments AB, CE, etc., are measured. It has not yet been shown, however, how to measure ares of a circle, i.e. how to

each are as AC, a number x may be attached, as its measure.

This will be given later No inconvenience can arise if we assume here a knowledge of this theory maximuch as the reader is perfectly conversant with its results, which are all we need for the present. Area measured in the direction of the arrow are positive, those

measured in the opposite direction are negative

If we suppose the point C to move around the circle in a positive direction starting from a fixed point A as point of reference it has described an arc whose measure is 2π .

$$\pi = 3 14159265$$

when it reaches A again. If it still continues moving around the circle it has described an arc $=4\pi$ when it reaches A for the second time. On reaching A for the third time the arc described is 6π etc. Thus to each positive number in \Re corresponds and, also conversely, to each arc measured in the direction of the arrow corresponds a positive number in \Re .

With arcs measured in the negative direction are associated the negative numbers of % and conversely

202 From this mode of defining the circular functions we conclude at once the following properties

The domain of definition of $\sin x$, $\cos x$ embraces all the numbers of \Re

The domain of definition of tau x embraces all numbers of \Re except

$$\frac{\pi}{9} + m\pi$$
, (1

 $\frac{2}{2} + m\pi,$ where $m = 0 \pm 1 \pm 2$

In fact for these ares, the secant OB is parallel to the tangent line AB and therefore cuts off no segment on it. Thus for these values of the argument x tan x is not defined.

Similarly, sec z is not defined for these same values 1), while cosec z is not defined for

$$x = m\pi$$
 $m = 0, \pm 1, \pm 2$. (2)

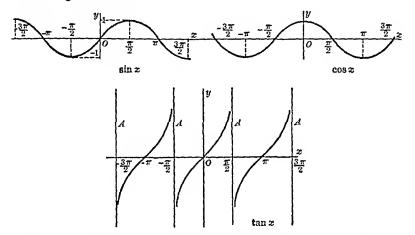

From similar triangles we have for all x, except these singular values in 1) or 2)

$$\tan x = \frac{\sin x}{\cos x}, \sec x = \frac{1}{\cos x}, \csc x = \frac{1}{\sin x}$$

We observe that these relations involve division by 0, for the singular values 1) or 2).

From the above definition of the circular functions we see that they are one-valued functions of x.

203. The graphs of the three principal functions $\sin x$, $\cos x$, $\tan x$, are given below.

204. The next most important property of the circular function is their *periodicity*.

In general we define thus:

Let ω be a constant $\neq 0$. Let f(x) be a one-valued function whose domain of definition D is such that, if x is any point of D, so is

$$x + m\omega, \qquad m = \pm 1, \ \pm 2, \ \cdots$$
If
$$f(x + \omega) = f(x)$$
(1

for every x in D, we say f(x) is periodic, and admits the period ω . If ω is a period of f(x), so is $m\omega$.

For,
$$m = \pm 1, \pm 2, \cdots$$
$$f(x+2\omega) = f[(x+\omega) + \omega] = f(x+\omega) = f(x),$$

hence 2ω is a period. Similarly, 3ω , 4ω , ... are periods. On the other hand,

$$f(x-\omega) = f((x-\omega) + \omega) = f(x).$$

Hence f(x) admits the period $-\omega$, and so $-2\omega - 3\omega$ etc If all the periods that f(x) admits are multiples of a certain period $\tilde{\omega}$, this is the primitive period of f(x) or the period of f(x)From trigonometry we have

The versed of sin x cos x, is 2 m, the period of tan x is w

205 1 If f(x), g(x) admit the period a, then

$$f(x) \pm g(x)$$

$$f(x)g(x) = \frac{f(x)}{g(x)} \quad g(x) \neq 0,$$
(5)

(2

admit also the period w

For example, let

$$h(x) = f(x) + g(x)$$

Ne bave

$$h(x+\omega) - f(x+\omega) + g(x+\omega) = f(x) + g(x) = h(x)$$

2 If the period of f(x) is we the period of f(ax) is . Here a ın anu number = 0

For, let

This gives setting

$$g(x) = f(ax),$$

and let τ be any period of g(x)Then

$$g(x+\tau) = g(x),$$

$$f(a(x+\tau)) = f(ax)$$

D£

ax = t $f(t+a\tau) = f(t)$

Thus $a\tau$ is a period of f(x), and therefore

Hence $\tau = m \frac{dr}{\sigma}$ 63

m an integer

As $\frac{\omega}{x}$ is obviously a period of g(x) it is the period of g(x), by 3)

3. Suppose in 1, that ω , instead of being any period of f and g, is the period of these functions. It is important to note that we cannot infer that therefore ω is the period of the functions in 1), 2).

$$f(x) = \sin x, \quad g(x) = 4\sin x \cos^2 x.$$

The period of these functions is 2π .

Yet the period of

$$h(x) = g(x) - f(x) = \sin 3x$$

 $ls \frac{2\pi}{3}$.

Ex. 2. Let

$$f(x) = \sin x, \ g(x) = \cos x.$$

Then

$$h(x) = f(x)g(x) = \frac{1}{4}\sin 2x.$$

The period of f and g is 2π ; the period of h is π .

Ex. 3. Let f(x), y(x), be as in Ex. 2. Let

$$h(x) = \frac{f(x)}{g(x)} = \tan x.$$

The period of h is again π .

Ex. 4. Let

$$f(x) = \sin^2 x, \quad g(x) = \cos^2 x.$$

The period of f, g is π .

But

$$h(x) = f(x) + g(x) = 1,$$

which has no primitive period.

206. From the periodicity of the circular functions we can prove that

The circular functions are transcendental.

Consider, for example,

$$y = \sin x$$
.

If this is algebraic, let it satisfy the irreducible equation

$$y^{n} + R_{1}(x)y^{n-1} + \dots + R_{n}(x) = 0.$$
 (1)

Replace here x by $x + 2m\pi$, m an integer.

If we set

$$R_{\kappa}(x+2\,m\pi)=T_{\kappa}(x),$$

gives, since y is unaltered,

$$y^{n} + T_{1}(x)y^{n-1} + \dots + T_{n}(x) = 0.$$
 (2)

As y satisfies both 1) and 2), it satisfies their difference

$$(R_1 - T_1)y^{s-1} + + (R_s - T_s) = 0$$

Thus y satisfies an equation of degree < n, which is not an identity. As we assumed 1) is irreducible this is a contradiction

207 Another important property of the circular function is their addition theorem which is expressed in the formulæ

$$\sin(x+y) = \sin x \cos y + \cos x \sin y,$$
$$\cos(x+y) = \cos x \cos y - \sin x \sin y,$$

 $\tan (x+y) = \frac{\tan x + \tan y}{1 - \tan x \tan y},$

203 I Let f(x) be a one valued function whose domain of definition, D, is such that if x is any point of D so is -x

Let
$$f(-x)-f(x)$$

for every x in D . We say, then, that f(x) is an even function if

$$f(-z) = -f(z),$$

we say f(x) is an odd function Obviously,

The functions an x tan x are odd while cos x is even

2 Letting 0 0₁ 0₂ represent odd functions, and E E_1 , E_2 even functions, we have

$$\begin{split} \mathcal{O} \pm \mathcal{O}_1 &= \mathcal{O}_2, \quad E \pm E_1 = E_2, \\ \mathcal{O} \quad \mathcal{O}_1 &= E_2, \quad E \quad E_1 = E_1, \quad \mathcal{O} \quad E = \mathcal{O}_1, \end{split}$$

$$\frac{O}{E} = O_1 \qquad \frac{E}{O} = O_1$$

For example

$$\theta_1(-x) = \theta(-x) \pm \theta_1(-x) = -\theta \mp \theta_1 = -(\theta \pm \theta_1) = -\theta_1$$

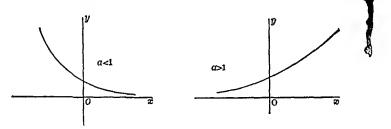

The Exponential Functions

209. Let a > 0 be a constant; the exponential functions are defined by $v = a^x$.

The domain of definition of y is \Re , and y is a one-valued function.

When a = 1, the corresponding exponential function reduces to a constant, viz.: y = 1.

The graphs of y fall into two classes, according as $a \ge 1$.

An important exponential function is that corresponding to a=e. $e=2.71818\cdots$

210. 1. The only properties of the exponential functions which we care to note now are the following:

The exponential function is nowhere equal to 0, or any negative number.

See 165, 2.

2 The addition theorem is expressed by

$$a^x a^y = a^{x+y}$$
.

One-valued Inverse Functions

211. 1. The two remaining classes of functions, viz. the logarithmic and inverse circular functions, are inverse functions. Before considering them, we wish to develop the notion of *inverse functions* in general.

2 Let f(x) be a one valued function defined over a domain D^*

If
$$f(x'') > f(x')$$

for every pair of values x'' > x' in D, we say f(x) is an increasing function in D

If on the contrary

$$f(x') < f(x'), \quad x' > x',$$

we say f(x) is a decreaming function

If f is either an increasing of a decreasing function in D, but we do not care to specify which we say it is univariant

These definitions are extensions of those given in 108. The corresponding extension of the terms monotone, monotone sucreasing, monotone decreasing to function is obvious

3 Ex 1 For the domain $D = \left(-\frac{\sigma}{2}, \frac{\pi}{2}\right)$ is πx is an increasing function. For the domain $D = \left(\frac{\pi}{2}, \frac{3\pi}{2}\right)$ sin x is a decreasing function.

Ex.2 For the domain $D-\Re$ of is an increasing function if a>1 it is a decreasing function if a<1. Thus whether $a\geq 1$ of is a univariant function in \Re .

212 Let
$$y = f(x)$$
 (1

be a one valued univariant function, defined over a domain D Let E be the domain over which the variable y ranges

We put the points of D and E in correspondence with each other as follows two points x, y shall correspond to each other, or be associated when they satisfy 1)

Then to a given recorresponds only one y since f(x) is one valued. On the other hand, to a given y corresponds only one x since f(x) is univariant

Thus to any x of D corresponds one, and only one, y of E conversely, to any y of E corresponds one, and only one x of D

213 The considered as of the last article have led us to one of the most important notions of modern mathematics, that of correspondence

• Such an expression as this will be constantly employed in the future. It does not mean that D includes all the values for which f(x) may be defined but only each values as one chooses to consider for the moment.

Let A and B be two sets of objects. Let us suppose that A and B stand in such a relation to each other, that to any object a of A correspond certain objects b, b', b'', \cdots of B: and to any object b of B correspond certain objects a, a', a'', \cdots of A.

Then A and B are said to be in correspondence.

If to each a corresponds only one b, and conversely, the correspondence is one to one (1 to 1), or uniform.

If to each a correspond m objects of B, and to each b correspond n objects of A, the correspondence is m to n.

In many cases, to each element of A correspond an infinity of objects of B, or conversely.

214. Let us return to 212. The correspondence we established between the points of D and E is uniform. This fact may be used to define a one-valued function g(y), over the domain E. In fact, let x correspond to y. Then g(y) shall have the value x, at the point y. Then x = g(y).

The function g, just defined, is called the *inverse function of* f. Evidently g is a one-valued function in E. It is also univariant.

In fact, to fix the ideas, suppose f is an increasing function.

Then, if

x' < x''

we have

$$y' < y''$$
.

Suppose now g were not an increasing function. Then for at least one pair of points,

 $y' < y'', \tag{1}$

we would have

$$x^{l} \leq x^{l}$$
.

We cannot have x' = x''; for then y' = y'', which contradicts 1). We cannot have x' > x''; for then y' > y'', which again contradicts 1).

We have thus the theorem:

Let y = f(x) be a one-valued univariant function, defined over a domain D. Let E be the domain of the variable y. Then the inverse function, x = g(y), is one-valued and univariant in E.

215 The notion of inverse functions developed in 212 and 214 is quite general. It will perhaps assist the reader if we take a very simple case

For the domain D let us take an interval I=(a, b) for f(x), let us take an increasing function, with graphs as in the figure The domain of y is then the enterval J=(a, b). That the correspondence between the points of I and I, as defined in 212, is uniform, is eeen here at once I or, to find

the points g corresponding to a given x, we erect the ordinate at x. This cuts the graph but once, viz. at P. There is thus but one point y in J corresponding to the point x in I.

Similarly, to find the points x corresponding to a given y, we draw the abscissa through y

This cuts the graph but once, vix at P

There is thus but one point x in I corresponding to a given y in J. That the inverse function is one valued, and is an increasing function in J, is at once evident from the figure

The Logarithmic Functions

216 1 We saw in 209 that the exponential functions

$$v=a^r$$
, $a>0$, $\neq 1$

are one-valued univariant functions for the domain \Re The domain of the variable y is the interval $I=(0^{\circ},+\infty)$ See 188

admain of the variable y is the interval $I=(0^+, +\infty)$ See 188. Then, by 214, the inverse of the exponential functions are one valued univariant functions, defined over I By 174, these inverse functions are

$$z = \log_2 v$$
. (1

and are called logarithmic functions with base α . In higher mathematics it is customary to take a = a = 2.71818. When

no ambiguity can arise, we may drop the subscript a in 1). Unless otherwise stated, we shall suppose the base is e.

2. The graph of the logarithmic function

$$y = \log x$$

is given in the figure.

3. The only other property of $\log x$ which we wish now to mention is their addition theorem,

0 1

$$\log xy = \log x + \log y.$$

Many-valued Inverse Functions

217. The eircular functions give rise to many-valued inverse functions. It is easy to extend the considerations of 212 and 214 so as to arrive at the notion of many-valued inverse functions in all its generality.

Let

$$y = f(x) \tag{1}$$

be a one or many valued function, defined over a domain D. Let the domain of the variable y be E. We put the points of D and E in correspondence as follows: two points x, y shall correspond to each other or be associated when they satisfy 1). Then, to each y of E correspond one or more values of x, say

$$x, x', x'', \dots$$
 (2)

We define now a function g(y) over E by assigning to g the values 2) of x associated with each point y of E.

Then

$$x = g(y) \tag{3}$$

is the inverse function, defined by 1).

The equation 3) may be considered as the solution of 1) with respect to x.

218 To illustrate the rather abstract considerations of the last article let us consider the following simple case from a geometric standpoint

Let the graph of

$$y=f(x)$$

be that in the figure Then $D = (a \ b)$ and $E = (a \ \beta)$

The createst number of values of v for a given z in D is 3 Hence y is a three valued function Let y be a point of E To and the points of D associated with it we draw the abscissa through y Let it cut the curve in the points P P' P' The projections x x' x of these points P on the x axis are the points sought

The greatest number of values z corresponding to any y of E is 4 Hence the inverse function

z = q(y)is a four valued function

219 I et us consider the function y = f(x) defined by

Or

 $x^2 - y^2 - 1 = 0$ $y = \pm \sqrt{x^3 - 1}$

Its graph given in the figure is a byperbola

To a value of x > 1, or x < -1 correspond two values of v marked w and w in the figure The domain D of z is marked heavy in the figure, and embraces all the points of the x axis, except (-1 1 1) The domain E of w is the whole waxis

To any point y of E correspond two values of x falling in D The inverse function x = q(y) thus defined is a solution of 1)

or 2) with respect to z. viz

$$z = \pm \sqrt{1 + y^2}$$

The correspondence which the equations 1) or 2) establish between the points of D and E is a 2 to 2 correspondence

220. The preceding example illustrates the fact that

The inverse of an algebraic function which is not a constant is an algebraic function.

To prove this theorem, let y=f(x) be defined by

$$P_0(x)y^n + P_1(x)y^{n-1} + \dots + P_n(x) = 0, \tag{1}$$

where the P's are polynomials in x, with constant coefficients.

The inverse function

$$x = g(y) \tag{2}$$

also satisfies 1). Let us arrange 1) with respect to x. If m is the highest degree of x in this equation, we get

$$Q_0(y)x^m + Q_1(y)x^{m-1} + \dots + Q_m(y) = 0.$$
 (3)

As 2) satisfies 3), the inverse function 2) is an algebraic function also.

In this example, y = f(x) is, in general, an n-valued function, while x = g(y) is an m-valued function.

The correspondence that the equation 1) or 3) establishes between the points of D and E, the domains of the variables x, y, is thus an n to m correspondence.

The Inverse Circular Functions

221. These are the functions

$$\sin^{-1}x$$
, $\cos^{-1}x$, $\tan^{-1}x$, etc.

We prefer to follow continental usage, and denote them respectively by

Arc $\sin x$, Arc $\cos x$, Arc $\operatorname{tg} x$, etc.

We shall not take the space needed to treat all these functions; we take one of them, Arc sin, as an illustration. The others may be treated in the same way.

We start with the equation

$$y = \sin x, \tag{1}$$

whose graph is given in 203.

138 ELEMENTARY FUNCTIONS NOTION OF A FUNCTION

The domain D, over which sing is defined, is R, the domain of

y is E = (-1, 1)Let y be a point of E If x_0 is one of the associated points of D, all the points of D associated with y are given by

$$x_0 + 2m\pi$$
 (2
 $m = 0 \pm 1, \pm 2$
 $-x_1 + 2m\pi$, (3)

as is shown in trigonometry

Thus, to a given value of y there are a double infinity of values of x

The inverse function defined by 1), viz

$$z = \text{Arc sin } y$$
,

has the interval E=(-1,1) for its domain of definition. It is an infinite valued function whose values for a given y are given in 2). 3)

222 The graph of

$$y = \operatorname{Arc} \sin x$$

is given in the adjoining figure.

The reader will observe that this griph can be got at once from the graph of ana x (see 203) by turning it around and changing the ares.

This property is obviously true of the graph of any inverse function

Thus, if the graphs of

are given, we may get at once the graphs of

223 The treatment of many valued functions is much simplified by employing the notion of a branch of the function This will be explained when we have considered the notion of continuity. For the present however we wish to define what are called the principal branches of the inverse causaliar functions.

Looking at the graph of Arc sin z given in 222, we see we can

define a one-valued function over the interval (-1, 1) by taking those values of Arc sin x which fall in the interval $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$.

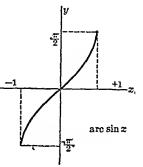

Its graph is given in the adjoining figure.

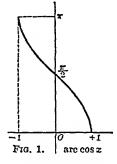

The one-valued function so defined over the interval (-1, 1) is denoted by arc $\cos x$.

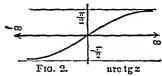

Its graph is given in Fig. 1.

2. The principal branch of Arctg x is formed of those values of this function which fall in the interval $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$.

The one-valued function so defined over $(-\infty, \infty)$ is denoted by arc $\lg x$.

Its graph is given in Fig. 2.

FUNCTIONS OF SEVERAL VARIABLES

The Rational and Algebraic Functions

225. In the list of the elementary functions given in 186, the first three, viz. the integral rational, the rational, and the algebraic functions, are, in general, functions of several variables.

For simplicity we treated them first as functions of a single variable. We wish now to define them in all their generality. At the same time we shall consider the general notion of functions of several variables and certain related geometric ideas.

226 1 An integral rational function of n variables $x_1 \ x_2 \ x_3$ is an expression of the type

$$y = Ax_1^{m_1}x_2^{m_2} \quad x_4^{m_3} + Bx_1 x_2^{l_2} \quad x_4^{l_3} + \dots + Lx_1^{l_1}x_2^{l_2} \quad x_5^{l_4}$$
 (

Here A B L are constants and the exponents m l e are positive integers or 0 Such functions are

$$2x_1^2x_2 + x_3 + 5x_1x_2x_3 (2$$

 $ax_1x_2^2x_3 + bx_2^5x_3 + ex_3^6 + dx_1x_2^5x_3$ (3)

We may write 1) in the form

$$y = \sum A_{m m_{\gamma} - m_{\alpha}} x_1^{m_{\gamma}} x_3^{m_{\gamma}} - x_s^{m_{\gamma}}$$
 (4)

where the summation extends over all the terms of y

A still all order notation is

$$y = \sum Ax_1^m x_2^{m_1} - x_4^{m_2}$$
 (5)

which may be employed when no simbiguity can arise.
The greatest of all the sums of the exponents

is the degree of v

Thus the degree of ?) 14 3 the degree of 3) 15 13

2 When the degree of each term of 1) is the same, it is said to be homogeneous

Let
$$F = \sum Ax_i^m x_i^{m_i} = x_i^{m_i}$$

be homogeneous and of degree m If in F we replace x_1 by λx_1 , x_n by λx_n and denote the result by F we have

$$\vec{F} = \lambda^n F$$

For,

$$\vec{F} = \sum A \lambda^{m+-+m_n} x_1^m \qquad x_n^{m_n}$$

But, for all the terms of F,

$$m_1 + \cdots + m_n = m$$
.

Hence

$$\overline{F} = \lambda^m \sum A x_1^{m_1} \cdots x_n^{m_n} = \lambda^m F.$$

3. When y is of degree 1, we have

$$y = a_1 x_1 + a_2 x_2 + \dots + a_n x_n + a_0$$

It is said to be a linear integral function of the x's. If $a_0 = 0$, it becomes $y = a_1x_1 + \cdots + a_nx_n$,

which is the general type of a linear homogeneous integral function of the x's.

In algebra, integral rational functions are called polynomials.

227. 1. To get a value of

$$y = \sum A x_1^{m_1} \cdots x_n^{m_n} \tag{1}$$

we give to each of the variables x a certain numerical value, as,

$$x_1 = a_1, \quad x_2 = a_2, \quad \cdots \quad x_n = a_n.$$
 (2)

These values put in 1) give the corresponding value of y, say y = b.

When n = 1, 2, 3, we can represent geometrically the values 2) by a point on a right line, a point in a plane, or a point in space, respectively, viz. the point a whose coördinates are a_1 , or a_1 , a_2 , or a_1 , a_2 , a_3 . If we give the x's different sets of values, we get different points in 1, 2, or 3 dimensional space. As in the case of one variable, we can say y has the value b at the point a.

2. It is convenient to extend these and other geometric terms, employed when the number of variables n = 1, 2, 3, to the case when n > 3. Thus any complex of n numbers, $a_1, a_2, \dots a_n$, is called a *point*; a_1, a_2, \dots are called its *coördinates*. We denote the point by $a = (a_1, a_2, \dots a_n).$

The aggregate of all possible points, the x's running over all the numbers in \mathfrak{R} , we call an n-dimensional space or an n-way space; and denote it by \mathfrak{R}_n . Later we shall extend the terms distance, sphere, cube, etc., to \mathfrak{R}_n . Cf. 244. The reader is not to

suppose for a moment that there really is an π dimensional space or an π dimensional cube, in the ordinary empirical sense of the word, but to bear in mind that these terms are merely names for certain numerical aggregates

3 Employing this geometrical language we may say that,

The integral rational function of several variables say n variables, is a one valued function whose domain of definition embraces all the points of R.

228 As in the case of one variable, the ritional function of several variables is the quotient of two integral rational functions in these variables. Its general expression is therefore,

$$R = \frac{\sum Ax_1^n}{\sum Bx_2^n} \frac{x_2^n}{x_2^n} = \frac{F}{G}$$
(1)

Its domain of definition embraces all the points of \Re_n except those osints at which G vanishes, which we call poles of R. For all points if this domain, R is one valued function

If m' is the degree of F, and m'' is that of G, the degree of R is the greater of the two integers m' m''

When the degree of R is I, it is called a linear rational function is general expression is

$$\frac{a_0 + a_1 x_1 + \dots + a_n x_n}{b_n + b_n x_n + \dots + b_n x_n} \tag{2}$$

We say R is homogeneous when F and G are homogeneous te have evidently, as in 226, 2

$$R(\lambda x_1, \lambda x_2, \lambda x_n) = \lambda^t R(x_1, x_n),$$
 (3)

where t is an integer, positive, negative, or zero

229 The definition of an algebraic function of n variables is an obvious extension of that given for one variable, in 197 Thus y is an algebraic function of x_1, x_2, \dots, x_n when it satisfies an equation of the type

 $y^{n} + R_{2}y^{n-1} + + R_{n-1}y + R_{n} = 0, (1)$

where the coefficients R are rational functions of $x_1 - x_n$, and n is a positive integer

Thus y is at most an n-valued function. Its domain of definition embraces all points of \Re_n except the poles of the coefficients R, and those points for which 1) has no real root.

Functions of Several Variables in General

230. We can give now the definition of a function in n variables. Let $x = (x_1, x_2, \dots x_n)$ range over the points of a certain domain D, viz. over \Re_n or a part of it. Let a law be given which assigns to y one or more values for each point of D. We say y is a function of $x_1, x_2, \dots x_n$, and write

$$y = f(x_1 \cdots x_n)$$
, or $y = \phi(x_1 \cdots x_n)$, etc.

When no ambiguity can arise, we may even write

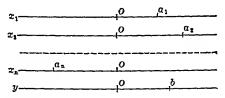

$$y=f(x), y=\phi(x), \text{ etc.},$$

where x stands for the n variables $x_1 \cdots x_n$.

The meaning of the terms of 189, viz. one-valued and many-valued, independent variables or argument, dependent variable, domain of definition of the function, when applied to several variables, needs no explanation.

231. We explain now the graphical representation of functions of several variables.

We take n+1 axes, one for each of the variables $y, x_1, x_2, \dots x_n$.

The representation of a point $x_1 = a_1 \cdots x_n = a_n$, is a complex of n points $a_1 \cdots a_n$, as in the figure. The value of y, say y = b, is represented by the point b on the y-axis. This representation, although unsatisfactory in some respects, is still often useful.

144 FLENENTARY PUNCTIONS NOTION OF A FUNCTION

232 When n = 2 we have two other modes of representation. Let the function be

$$y=f(x_1 \ x_2)$$

We take three axes x_1 x_2 y as in any lytic geometry of three dimensions. To the set of values of the independent variables

$$x_1 - a_1$$
 $x_2 = a_2$

corresponds the point $a-(a_1 a_2)$ whose coordinates are $a_1 a_2$. The value b of y at the point we lay off on the ordinate through a. As r runs over its domain D y will ordinarily trace out a surface in \Re .

233 The other mode of representation is by means of a plane and an axis

The domain of the independent variables we represent by points in the x₁x₂ tlane while y is represented by points laid off on a separate axis as in the figure

234 When n = 3 we may employ the following representation Let.

$$y = f(x_1 x_2 x_3)$$

be defined over a domain D

To represent D we take three rec tangular axes

To the set of values

$$x_1=a_1 \quad x_2=a_2, \quad x_3=a_3$$

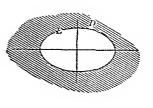

corresponds the point a whose coordinates are a_1 a_2 a_3 . The values of y we lay off on a separate axis a_3 in the figure

235 From the elementary functions of one variable we can build an infinity of functions of everal variables. We give some examples which illustrate the various domains of definition that a function of several variables may have. We shall take n = 2

$$z = \log\left(\frac{x^2}{a^2} + \frac{y^2}{b^2} - 1\right)$$

For points within the ellipse E, whose equation is

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - 1 = 0,$$

the argument of z is negative. For points on E the argument is 0. As the logarithmic function is defined only for positive values of the argument, the domain of definition D, of z, is the region shaded in the figure. Its edge, or E, does not belong to D.

$$z = \log\left(\frac{x^2}{a^2} + \frac{y^2}{b^2} - 1\right)\left(\frac{x^2}{a^2} - \frac{y^2}{\beta^2} - 1\right) = \log uv.$$

Since $\log uv$ is not defined, nuless uv > 0, u and v must be both positive, or both negative. The domain of definition D, of z, is thus the region shaded in the figure. Since

w = 0 on the edge of D, these points do not belong to D.

$$z = \tan \frac{1}{2} \pi x y.$$

Since tan u is not defined when

$$u = \frac{\pi}{2} + m\pi,$$

 $m = 0, \pm 1, \pm 2, \dots$

we see the domain of definition of z includes all the points of the xy plane, except a family of hyperbolas xy = 2m + 1.

Composite Functions

238. 1. An extremely useful notion in many investigations is that of a function of functions, or composite functions. Let

$$u_1 = f_1(x_1 \cdots x_n) \qquad u_m = f_m(x_1 \cdots x_n)$$

be defined over a domain X in a dimensional space R. Let

$$u = (u_1 u_1 \quad u_n)$$

be a point in an m dimensional space R.

While z runs over X, let s run over a domain U Let

$$y = \phi(u_1 \quad u_n)$$
 (1)

be defined over U. Then y is defined for every point z in X. We may, therefore, consider y as a function of the x s through the u's. We say y is a function of functions, or a composite function

- 2 When speaking of composite functions, we shall always suppose, even without further mention that the domain of definition of 1) is at least as great as U
- 2 When x ranges over X u. as we said, runs over the domain

When x ranges over X u, as we said, runs over the domain U It is convenient for brevity to call U the image of X

$$w_1 = x_1x_2$$
 $w_1 = \sec x_1$ $w_2 = e^x_4$

 $y = \log u_1 + \tan \frac{u_2}{u_1}$ Here u_1 us are defined for all the points of \mathfrak{R}_2 for which

while y is defined for all the points of R. for which

239 The notion of a composite function is sometimes useful in transforming a function as follows. Let

$$y = F(z_1 \quad z_n)$$

we set $u_i = \phi_i(x_1 \quad x_s)$ $u_s = \phi_w(x_1 \quad x_s)$

y goes over into

$$y = G(u_1 \quad u_m)$$

Let

$$y = a \frac{x_1^2}{x_2^2} + \frac{x_1^2 + x_2^2}{x_1^2 - x_2^2} + \log \frac{x_1}{x_2} = F(x_1, x_2)$$

then

$$u = \frac{x_1}{x_1}$$

$$y = au^2 - \frac{1 + a^2}{1 - a^2} + \log u = G(u)$$

Limited Functions

240. Let $f(x_1 \cdots x_m)$ be defined over a domain D. If there exists a positive number M, such that

$$|f| \leq M$$

for every point of D, f is said to be finite or limited in D; otherwise f is unlimited in D.

Ex. 1.

 $f(x) = \sin x$.

Since

 $|\sin x| \le 1$, x arbitrary.

sin x is a limited function for any domain.

Ex. 2.
$$f(x) = a_0 + a_1 x + \cdots + a_n x^n, \quad a_n \neq \infty$$

is limited in any domain (-G, G), where G is some fixed positive number. It is unlimited in the domain $(0, +\infty)$, for example.

Ex. 3.

$$f(x) = \frac{1}{x}$$

Is defined for every $x \neq 0$.

It is limited in any domain as (a, ∞) , if a < 0.

It is unlimited in (0*, 1), for example.

241. Let $f(x_1 \cdots x_n)$, $g(x_1 \cdots x_n)$ be limited functions in a domain

D. Then

$$f \pm g$$
, fg

are limited in D.

If

in D, then

$$\frac{f}{a}$$

is limited in D.

Since f, g are limited in D, let

$$|f|, |g| < M$$
.

Then

$$|f \pm g| \le |f| + |g| < 2M$$
.

Hence $f \pm g$ is limited in D.

Also

$$|fg| = |f| \cdot |g| < M^2.$$

Hence fg is limited in D.

Finally,

$$\left|\frac{f}{g}\right| = \frac{|f|}{|g|} < \frac{M}{g}$$

Hence $\frac{f}{g}$ is limited in D.

CHAPTER V

FIRST NOTIONS CONCERNING POINT AGGREGATES

Preliminary Definitions

242 In elementary mathematics the functions employed are smally defined by simple analytic expressions. Their nature is simple, and their domains of definition receive little attention. In the theory of functions we take a higher standpoint, and consider functions defined by any last, as explained in 189 and 230. Such functions are not title down to an analytic expression, indeed, we may not know how to form their analytic expression.

From this point of view, the domain D over which the function is defined or spread out is often of great importance. Frequently we choose first the domain D, and then define a function for the points of D.

The domain of definition of a function of a variables may be any eet or aggregate of points in \$\mathbb{R}_a\$. We wish to treat now the most elementary properties of such aggregates which we call point aggregates.

243 1 Two point aggregates A, B are equal, when every point of A has in B, and every point of B has in A. In this case, we write

A = B

2 If every point of B hes in A but not every point of A hes in B, we say B is a partial or sub aggregate of A, and write

$$A > B$$
 or $B < A$

3 If A does not exist, 24 if it contains no points, we write

A = 0

As the symbol 0 also stands for the origin, we shall write, in case of ambiguity, A = (0).

when we wish to indicate that A consists of the origin alone.

The fact that A contains at least one point, we indicate by

$$A > 0$$
.

- 4. Let A, B be two point aggregates having no point in common. The aggregate formed by their reunion is called their sum, and is denoted by A + B.
- 5. If B is a partial aggregate of A, the aggregate formed by removing all the points of B from A is called the difference of A, B, and is denoted by A B.

It is also called the complement of B.

6. If a or x, for example, are general symbols for the points of an aggregate, we can represent the aggregate by

Thus, if $A = \frac{1}{2}, \frac{1}{2}, \frac{1}{3}, \cdots$ we can write $A = \left\{\frac{1}{n}\right\}.$ Or if $A = a_1, a_2, a_3, \cdots$ we can write $A = \{a_n\}.$

244. Definitions of configurations in n-way space. Cf. 227, 2.

1. Let $a = (a_1 \cdots a_n)$, $b = (b_1 \cdots b_n)$ be two points of \Re_n . We say

$$\sqrt{(a_1 - b_1)^2 + \dots + (a_n - b_n)^2} \tag{1}$$

is the distance between a, b; we denote it by

Dist
$$(a, b)$$
 or $\overline{a, b}$.

2. The points x satisfying

$$x_1 - a_1 = \lambda(b_1 - a_1) \quad \cdots \quad x_n - a_n = \lambda(b_n - a_n)$$
 (2)

lic on a right line L, viz. the line determined by the two points a, b. Here λ runs over all the numbers of \Re .

When $\lambda = 0$, x = a, when $\lambda = 1$, x = b Points x for which $0 \le \lambda \le 1$, form 1 segment or interval $(a \ b)$ of L Such points are and to be between $a \ b$

An aggregate lying on a right line is called rectilingar

3 If three points a, b, c he on a right line, we have from 2) that

$$\frac{c_s - \alpha}{b_s - a} = \frac{c_s - \alpha_s}{b_s - a_s}, \quad \iota = 1 \ 2, \quad n$$
 (3)

and conversely, if 3) holds, a, b, c he on a right line

4 Let a, b be two points on the line L and

Then

$$r = \text{Dist}(a, b)$$

$$\lambda_1 = \frac{a_1 - b_1}{a} \qquad \lambda_n = \frac{a_n - b_n}{a}$$

are the direction cosines of the line L. Obviously,

$$y_2^1 + + y_2 = 1$$

5 The points x defined by

$$(x_1 - a_1)^2 + + (x_2 - a_2)^2 = r^2, r > 0$$

lie on a sphere S whose center is a and whose radius is f.
The equation of S may also be written

$$Dist(a \ x) = r$$

The points x, such that

Dist
$$(a \ x) < r$$

he within S II Dist (a x) >r

6 The points x, such that

$$|x_1-a_1|\leq \tfrac{1}{2}\,\epsilon \qquad |x_n-a_n|\leq \tfrac{1}{2}\,\epsilon,$$

lorm a cube, with center a and edge e

7. The points x, such that

$$a_1 \leq x_1 \leq b_1 \quad \cdots \quad a_n \leq x_n \leq b_n$$

form a reetangular parallelopiped or cell whose edges are of length

$$e_1 = b_1 - a_1 \quad \cdots \quad e_n = b_n - a_n.$$

8. The eube

$$|x_1 - a_1| \le \frac{r}{\sqrt{n}} \quad \cdots \quad |x_n - a_n| \le \frac{r}{\sqrt{n}}$$

is called the *inscribed cube* C of the sphere S, of radius r, and eenter a.

Every point x of C is in S. For,

$$\sqrt{(x_1-a_1)^2+\cdots+(x_n-a_n)^2} \le \sqrt{\frac{r^2}{n}+\cdots+\frac{r^2}{n}} = r.$$

9. Let the cube C be given by

$$|x_1-a_1| \geq \frac{1}{2} \sigma \cdots |x_n-a_n| \geq \frac{1}{2} \sigma.$$

The points

$$v_1 = a_1 \pm \frac{1}{2} \sigma \quad \cdots \quad v_n = a_n \pm \frac{1}{2} \sigma$$

are called the vertices.

If

$$v = (v_1 \cdots v_n)$$

is one vertex,

$$v' = (-v_1 + 2a_1, \dots - v_n + 2a_n)$$

is called the opposite vertex.

The line joining a pair of opposite vertices evidently passes through the center of C. It is called a diagonal.

The length of a diagonal is

$$\sqrt{\sigma^2 + \dots + \sigma^2} = \sigma \sqrt{n}.$$

- 10. The distance between two points a, b in C is greatest when they are opposite vertices. For, each term $(a_i b_i)^2$ in 1) has then its greatest value, viz. σ^2 .
- 11. If $e_1, e_2, \dots e_n$ are the lengths of the edges of the parallelo piped in 6, we say the product

$$e_1 \cdot e_2 \cdots e_n$$

is its volume.

In case the parallelopiped is a cube of edge σ , its volume is σ^n .

12 The points x defined by

$$a_i x_i + + a_i x_i + d = 0 (4$$

he in a plane The two planes 4) and

are parallel

245 Let a, b, c be three points in R.

Let A = Dist(b, c) B = Dist(a, c), C = Dist(b, a).

H = Bist (0, t) B = Dist (a, t), C = Bist

When n = 1, 2, 3, we have

$$A \gtrsim B + C$$
 (1

Here the inequality sign holds unless 4, B, C he on a right line L

We show now that 1) holds for every n *
To this end, set

 $\alpha = \delta_i - c$, $\beta_i = a - c$, $\gamma = \delta_i - a_c$ where α_i , δ_i , c, $i = 1, 2, \dots$ are the coordinates of a_i , b_i , c

Then $\alpha = \beta + \gamma$ (2)

Now,
$$A^2 = \alpha_1^2 + \cdots + \alpha_n^2 = \sum \alpha_n^2$$
, $B^2 = \beta_1^2 + \cdots + \beta_n^2 = \sum \beta_n^2$, (3)

$$C^{2} = \gamma_{1}^{2} + + \gamma_{n}^{2} = \Sigma \gamma_{n}^{2}$$
 (4)

From 2), we have also

$$A^{2} = \Sigma(\beta + \gamma)^{2} = \Sigma\beta^{2} + \Sigma\gamma^{2} + 2\Sigma\beta\gamma, \quad (5)$$

Thus to prove 1), we have to show that

$$A^1 < B^2 + C^2 + 2BC$$

or, using 3), 4), 5) that

$$\Sigma\beta^2 + \Sigma\gamma^2 + 2\Sigma\beta\gamma \leq \Sigma\beta^2 + \Sigma\gamma^2 + 2\sqrt{(\beta_1^2 + \cdots + \beta_s^2)(\gamma_1^2 + \cdots + \gamma_s^2)}$$

• If the reader finds the demonstration difficult let him go through it, taking n-2 or 3. We recommend this in the case of any demonstration which the reader finds too hard for reneral n

This shows that it will suffice to prove that

$$(\Sigma \beta_{\iota} \gamma_{\iota})^{2} < \Sigma \beta_{\iota}^{2} \Sigma \gamma_{\kappa}^{2}. \tag{6}$$

To do this, we start from the inequality

$$(\beta_{1}\gamma_{x} - \beta_{x}\gamma_{x})^{2} \stackrel{?}{>} 0. \tag{7}$$

By 244, 3, the inequality sign holds for at least one pair of indices ι , κ , unless a, b, c lie on a right line.

From 7), we have

$$\beta_{\cdot}^{2}\gamma_{\cdot}^{2} + \beta_{\cdot}^{2}\gamma_{\cdot}^{2} = 2\beta_{\cdot}\beta_{\epsilon}\gamma_{\cdot}\gamma_{\epsilon}. \tag{8}$$

Let us form all the relations of this type, letting ι , κ run over the indices 1, 2, ..., n, and keeping $\iota \neq \kappa$.

If we add these, we get

$$\Sigma \beta_{\iota}^{2} \gamma_{\kappa}^{2} \geq 2 \Sigma \beta_{\iota} \beta_{\kappa} \gamma_{\iota} \gamma_{\kappa}. \qquad \iota \neq \kappa.$$
 (9)

On the other hand,

$$\Sigma \beta_{i}^{2} \cdot \Sigma \gamma_{\kappa}^{2} = (\beta_{1}^{2} + \dots + \beta_{n}^{2}) (\gamma_{1}^{2} + \dots + \gamma_{n}^{2}) = \Sigma \beta_{i}^{2} \gamma_{i}^{2} + \sum_{i \neq \kappa} \beta_{i}^{2} \gamma_{\kappa}^{2}.$$

Hence, by 9),

$$\Sigma \beta_{\iota}^{2} \cdot \Sigma \gamma_{\kappa}^{2} \equiv \Sigma \beta_{\iota}^{2} \gamma_{\iota}^{2} + 2 \sum_{\iota \neq \kappa} \beta_{\kappa} \gamma_{\iota} \gamma_{\kappa}. \tag{10}$$

But

$$(\Sigma \beta_i \gamma_i)^2 = (\beta_1 \gamma_1 + \dots + \beta_n \gamma_n)^2 = \Sigma \beta_i^2 \gamma_i^2 + 2 \sum_{i \neq \kappa} \beta_{\kappa} \gamma_i \gamma_{\kappa}.$$

This in 10) gives 6).

246. A point x for which Dist (a, x) is small, is said to be near a. What is to be considered as small, depends on the problem in hand.

The points x, such that

Dist
$$(a, x) < \rho$$
, $\rho > 0$.

form an aggregate called the domain of the point a, of norm ρ . It is denoted by $D_{\rho}(a)$, D(a), D_{α} .

For example, in \Re_1 , $D_{\rho}(a)$ is the interval $(a-\rho, a+\rho)$.

In \Re_2 , $D_{\rho}(a)$ embraces all points in a circle of radius ρ , and center a; in \Re_3 , it embraces all points in a sphere of radius ρ .

We sometimes wish to exclude the point a from its domain. When this is done, the domain is said to be deleted, we denote it by

$$D^*(a)$$
 or $D^*(a)$

247 Let A be a point aggregate in R.

Let p be any point in \mathfrak{R}_n . We say p is an inner point of A if every point in some domain of p hes in A, t e if there exists a $\rho > 0$ such that every point of $D_{\epsilon}(p)$ hes in A. The point p is an outer point of A if no point of $D_{\epsilon}(p)$ hes in A. A however small $\rho > 0$ is taken, there is at least one point of A and one point not in A. Every point of \mathfrak{R}_n , is either an inner, an outer, or a frontier point of A. The frontier points of a cube or paralleloniped form its surface.

Here any point p_1 such that $n < p_1 < \beta$ is an inner point. Any point p_2 such that $p_2 > \beta$ or $p_3 < \alpha$, is an outer point

Ex 2. A embraces the rational points in (a, β) . Here all points p such that p < n or $p > \beta$ are only points. The points of A are all frontier points. For if a be any point of A there are irrational points in every $D_p(a)$ however small a > 0 is taken by \$4

In this example A contains no inner points,

The frontier points are a and &

Ex. 3 A embraces all the points in \Re_2 both of whose coordinates are rational. Here every point p of \Re_2 is a frontier point. In fact, consider a little circle C of radius $\rho>0$ and center p. Evidently p contains points in A and points not in A, however analy as taken

In this example there are no outer and no inner points of A.

249 Let b be an inner point of

Then
$$S = D_{\sigma}(a)$$

$$\Delta = D_{\delta}(b)$$
thes within $S : f'$

$$\rho + \delta < \sigma,$$
where
$$\rho = \text{Dist } (a, b)$$

The theorem is proved if we show that the points y of Δ satisfy the relation $\text{Dist}(a, y) < \sigma$. (2)

But, by 245,

$$\mathrm{Dist}(a,y) \leq \mathrm{Dist}(a,b) + \mathrm{Dist}(b,y) = \rho + \delta.$$

Thus, by 1), the relation 2) is valid.

250. 1. Let A be a point aggregate, and p any point in \Re_n . The points of A, lying in $D_{\rho}(p)$, form the vicinity of p, of norm ρ . It is denoted by $V_{\rho}(p)$ or V(p).

Thus D(p) embraces all points near p, while V(p) includes only points of A, near p.

Example. Let $A=1, \frac{1}{2}, \frac{1}{3}, \cdots$

Here $D_{\rho}(0)$ is the interval $(-\rho, \rho)$, while $V_{\rho}(0)$ is the set of points

$$\frac{1}{m}, \frac{1}{m+1}, \frac{1}{m+2}, \dots$$

where m is the least integer such that $\frac{1}{m} \stackrel{=}{\geq} \rho$.

The point p may or may not lie in V(p). We sometimes wish expressly to exclude it. When this is done, the resulting aggregate is the *deleted vicinity of* p; it is denoted by

$$V_{\rho}^*(p)$$
 or $V^*(p)$.

251. When treating functions of a single variable x, we have often to consider the behavior of the function on one side of a point a. This leads us to split the domain and vicinity of a into two parts, forming a right and left hand domain; a right and left hand vicinity of a.

The right hand domain and vicinity we denote respectively by

The left hand domain and vicinity are denoted by

The point a lies in both the right and left hand domain. It lies in both the right and left hand vicinity if a lies in V(a). It should be remembered that these terms refer only to rectilinear aggregates.

252 1 A point aggregate is said to be finite when it contains only a finite number of points Otherwise it is infinite

A point aggregate A is said to be timited when all its points lie within a certain sphere or cube, having the origin as center

This definition is equivalent to saying that the coordinates a_p a_a , of every point of A, are numerically less than some positive number M If A is not limited, it is said to be unlimited Obycously Every finite convenants is limited.

Ex. 1 is an infinite unlimited appreciate

A=1, 2, 3, -

Ex 2 A=1, 1, 1, .

is an infinite limited aggregate.

Ex. 3 $A = points of the interval (<math>\alpha, \beta$) is an infinite limited aggregate

2 In the case of a rectilinear aggregate A, it may happen that the coordinates of all its points x are less than some number M We say A is limited to the right

If the coordinates of all the points x are greater than some number N, we say A is limited to the left

Ex 2 A = -5, -5, -2, -2, -1 0, 1, 2, 3, is limited to the left.

253 1 It is sometimes convenient to divide an interval into equal subintervals or a square into equal subsquares, and, in general, an m dimensional cube P into equal subcubes

- 2. Instead of a cube Γ in \Re_m , we may wish to divide the whole of \Re_m into cubes. The meaning of this is now evident.
- 3. Let A be any point aggregate in \mathfrak{R}_m . Let us divide \mathfrak{R}_m into cubes of side δ . This also, in general, divides A into partial aggregates. This division of A into partial aggregates we shall call a cubical division of A, of norm δ .
- 4. If instead of dividing \Re_m into cubes, we had divided it into rectangular parallelopipeds whose edges are $\geq \delta$, we shall say that we have effected a rectangular division of \Re_m of norm δ .
- 5. The partial aggregates, into which A falls after a cubical or rectangular division, may also be called cells.

Limiting Points

254. 1. One of the most important notions connected with point aggregates is that of a *limiting point*. Let A be a point aggregate in \Re_m . Any point p of \Re_m is a limiting point of A, if however small $\rho > 0$ is taken, $D_{\rho}(p)$ contains an infinity of points of A.

If every domain of p contains at least one other point, p is a limiting point of A.

For, let a be a point of A different from p. Let $0 . Then, by hypothesis, <math>D_p(p)$ contains some points a_1 of A, besides p. Let $0 < p_1 < \text{Dist}(p, a_1)$. Then $D_{p_1}(p)$ contains some point a_2 of A, besides p. Continuing in this way, we see that the infinite aggregate of distinct points

all lie in $D_{\rho}(p)$.

2. The following may also be taken as definitions of a limiting point:

If $V_{\rho}(p)$ is infinite, however small ρ is taken, p is a limiting point of A; or,

If $V_{\rho}^*(p) > 0$, however small ρ is taken, p is a limiting point of A.

3 If p is a limiting point of A and p itself lies in A, it is called a proper limiting point. If p is not in A, it is called an improper limiting point.

Any point of an aggregate A which is not a limiting point is an isolated point

4 Let A be a rectilinear aggregate, and a one of its limiting points. If no point of A falls in $(a^*a + b)$ or in $(a - b, a^*)$, b > 0 sufficiently, small, a is called a unilateral limiting point. Otherwise a is a bilateral limiting point.

Here the origin is a unilateral limiting point of A, As 0 does not lie in A it is an improper limiting point.

The origin is a proper unlisteral limiting point of A

Ex 3 A = totality of rational numbers.

Every point p in \Re is a bilineral limit of point.
If p is a rational point is an aproper l sixting point of A. If p is an irrational point, it is an improper limiting point, it is an improper limiting point.

Limiting Points connected with Certain Functions

256 We give now a few examples of point aggregates which come up in the study of certain functions

Let
$$y = \sin \frac{1}{x}$$

The domain of definition of this function embraces all points on the

x axis except x=0It oscillates between -1 and +1

The points $x = a_1 \ a_2 \ a_3$

for which y takes on a particular value, as y = 0, form a point aggregate whose limiting moint is z = 0

In any domain of this point, y oscillates from +1 to-1 an infinite number of times

257. Let

$$y = \sin \frac{1}{\sin \frac{1}{x}}.$$
 (1)

When x = 0, or when

$$\sin\frac{1}{x} = 0, (2$$

y is not defined, since for these points, 1) involves division by 0. The points x for which 2) holds are

$$\pm \frac{1}{\pi}, \pm \frac{1}{2\pi}, \pm \frac{1}{3\pi}, \dots$$
 (3)

This is a point aggregate whose limiting point is x = 0.

As x approaches one of the points $\frac{1}{n\pi}$, y oscillates with increasing rapidity. At the same time these points, $\frac{1}{n\pi}$, become infinitely dense as x nears the origin. The domain of definition of y is the x-axis except the origin and the points 3).

258. Let

$$y = \sin \frac{1}{\sin \frac{1}{\sin \frac{1}{x}}}.$$

This expression does not define y, because of division by 0, when

$$x=0, (1$$

or when x satisfies

$$\sin\frac{1}{x} = 0, \tag{2}$$

or

$$\sin\frac{1}{\sin\frac{1}{x}} = 0. \tag{3}$$

The points x defined by 1) and 2) are

$$A = 0, \pm \frac{1}{\pi}, \pm \frac{1}{2\pi}, \dots$$

considered in 257.

It is easy to see that the points # defined by 3) form an aggregate B such that each of the points of A is a limiting point of B In fact, let x approach the point $\pm \frac{1}{8\pi}$. As it does so, $\sin \frac{1}{x}$ becomes smaller and smaller, hence $\frac{1}{\sin x}$ becomes larger and larger.

Thus in the domain of this point $\pm \frac{1}{\pi \pi}$.

oscillates infinitely often between - 1, 1, and in particular 3) is satisfied infinitely often Thus, the domain of definition of y includes all points of the

x axis except the points A and B About each point of B, y oscillates infinitely often These

points of infinitely frequent oscillation, themselves cluster infi nitely thick about each point of A, while the points A cluster infinitely dense about the origin Let the reader try to picture to himself how the graph of y looks about the points

$$\pm \frac{1}{n\pi}$$
, and 0

253 I The functions of 257 and 258 are formed from that of 206 by a process of steration

In fact, let

$$y = \sin \frac{1}{x} = \theta(x)$$
,

then

$$\sin\left\{\frac{1}{\sin\frac{1}{z}}\right\} = \theta[\theta(z)]$$

Similarly.

$$\sin\left\{\frac{1}{\sin\frac{1}{2}}\right\} = \theta\{\theta[\theta(z)]\}, \text{ etc.}$$

It is customary to write

$$\theta^2(x)$$
 for $\theta[\theta(x)]$, $\theta^3(x)$ for $\theta[\theta^2(x)]$, etc.

2. As another example of iteration, let

$$y = \log x = \theta(x).$$

Then

$$\theta^2(x) = \log(\log x),$$

$$\theta^3(x) = \log[\log(\log x)]$$
, etc.

260. Let

$$y = \sin \frac{1}{x} = \theta(x)$$
.

We have noted the domain of definition of

$$\theta(x), \ \theta^2(x), \ \theta^3(x).$$

In general, let A_m be the domain of definition of $\theta^m(x)$. point of A_{m-1} is a limiting point of A_m , and $\theta^m(x)$ oscillates infinitely often about each point of A_m .

261. To get functions of two variables having more complicated domains of definition, we may apply the process of iteration to the function of 237.

Let
$$\theta(x\dot{y}) = \tan \frac{1}{2}\pi xy$$
.

We saw θ was not defined for points on the family of hyperbolas

family of hyperbolas

H)
$$xy = 2m + 1$$
, $m = 0, \pm 1, \pm 2, ...$

Let us consider the domain of definition D_2 of

$$\theta^2(xy) = \tan\left(\frac{1}{2}\pi \tan\frac{1}{2}\pi xy\right).$$

Through any point P of one of these hyperbolas H) pass an arbitrary right line L.

At any point Q on the line, such that

$$\theta(xy) = 2n + 1, \quad n = 0, \pm 1, \dots$$

 θ^{n} is not defined.

But the points Q have P as limiting point.

Dernatues of Point Aggregates

262 1 Let A be a joint aggregate. The limiting points of A if it has any form an aggregate which is called the first deriv at a of A and is denoted by A.

Ex 1
$$A = \begin{cases} 3 & 6 & 6 & 6 \\ 2 & 2 & 4 & 5 \end{cases} - \left\{ \frac{n+1}{n} \right\}$$

Ex 2 $A = \begin{cases} 1 & 3 & 4 & 1 & 6 & 1 & 6 \\ 2 & 2 & 3 & 3 & 4 & 6 & 6 \end{cases} = \left\{ \frac{1}{n} & \frac{n+1}{n} \right\}$

2 Wl en A is a finite aggregate

$$A = 0$$

But A may be infinite and jet have no derivative Ex 3

such an aggregate

263 I The first derivative A may have limiting points their aggregate is called the second derivative of A. It is denoted by A. A. n ay have limiting joints these give rise to the third deriv

at te A etc

and

Let m be arbitrary but fixed then $\frac{1}{m}$ s a limit ag point of A. For A contains the points

$$\frac{1}{m}+1$$
 $\frac{1}{m}+\frac{1}{m}+\frac{1}{m}+\frac{1}{m}+\frac{1}{m}+\frac{1}{m}+\frac{1}{4}$

whose i m ting point is obvously $\frac{1}{n}$

Thus, $A = \left\{ \begin{array}{c} m \\ 1 \\ m \end{array} \right\} \qquad m-1 \ 2 \ 3$ while

$$A = (0)$$
 (1)

As expla ued in 243 3 the equation 1) means that A consists only of the origin e indicates that A has no points at all.

Ex. 2. A = rational points in an interval I; A' = I. See 255, Ex. 3.

$$A^{\prime\prime}=I,\ A^{\prime\prime\prime}=I,\ \cdots$$

Thus A has derivatives of every order, each being L

2. If $A, A', \dots A^{(m)} > 0$, while $A^{(m+1)} = 0$, A is of order m.

- 264. Every limited infinite point aggregate has at least one limit ing point.
- 1. For simplicity let us consider first the case that the aggregate A lies in the interval I = (a, b). We divide I into halves. One of these halves, call it I_1 , contains an infinity of points of A. Divide I_1 in halves. One of these halves must contain an infinity of points of A. In this way we may continue bisecting each successive interval, without end. We get thus an infinite sequence of intervals I_1 , I_2 , I_3 , ... (1)

each lying in the preceding, whose lengths converge to 0.

By 127, 2, the sequence 1) determines a point α . This point α lies in every interval of 1). Since each $D(\alpha)$ contains some I_n , it contains an infinity of points of A. Hence α is a limiting point of A.

2. The extension of this demonstration to \mathfrak{R}_n is now readily made. Since A is limited, it lies in a certain parallelopiped P, viz., $a_1 \leq x_1 \leq b_1 \cdots a_n \leq x_n \leq b_n$,

by 252. We divide now P into two parts

 $a_1 \le x_1 \le \frac{1}{2}(b_1 - a_1), \ a_2 \le x_2 \le b_2 \cdots a_n \le x_n \le b_n,$ (2 $\frac{1}{2}(b_1 - a_1) \le x_1 \le b_1, \ a_2 \le x_2 \le b_3 \cdots a_n \le x_n \le b_n.$

In one of these there must lie an infinity of points of A. To fix the ideas suppose it is the parallelopiped 2) which we call Q_1 .

 Q_1 differs from P only in having one coördinate, viz. x_1 , restricted to an interval half as big as the original.

We now divide Q, into two parts,

and

 $a_1 \le x_1 \le \frac{1}{2} (b_1 - a_1), \ a_2 \le x_2 \le \frac{1}{2} (b_2 - a_2), \ a_3 \le x_2 < b_p, \cdots$ (3 and

$$a_1 \leq x_1 \leq \tfrac{1}{2} \, (b_1 - a_1), \quad \tfrac{1}{2} \, (b_2 - a_2) \leq x_2 \leq b_2, \quad a_8 \leq x_8 \leq b_2 ,$$

In one of these say it is the parallelopiped Q_2 defined by 3), an infinity of points of A must be Q_2 differs from P in having now two of its coordinates restricted to intervals only hall as large as the original ones

We may continue in this way restricting the remaining coordinates x_3 x_4 to intervals balf as big as the original ones. We get preallelopipeds Q_3 Q_4 Q_6 in each of which he an infinity of points of A

Let us set $P_1 = Q_s$ This parallelopiped lies in P and has each edge just half as big as the corresponding edge of P We may now subdivide P_1 just as we did P. After n bisections

we get a parallelopuped P_2 which has in P_1 which contains an infinity of points of A and whose edges are one half as big as those of P_1

Continuing this process indefinitely we get a sequence of paral lelopipeds

P. P. P.

which determines a point $\alpha = (\alpha_1\alpha_2 - \alpha_3)$ This point is evidently a limiting point of A by the same reasoning as employed in I

265 If A is a limited aggregate of the nth order A^o is finite for if A^a were infinite, being limited it must have at least one limiting point by 264. Then $A^{a-b}>0$ which contradicts the bypothesis.

266 Let A be any point aggregate Then $A \leq A$ is all the limiting points of A are proper

1 For simplicity, let us first consider a rectilinear aggregate

Let p be any point of A', we lay it off on the A, A' axes also as in the figure

To show that p lies in A', we have to show it is a limiting point of A, i.e. in any little interval K about p there lie an infinity of points of A. Let I be any little interval about p on the A' axis. As p is a limiting point of A', I contains an infinity of points of A'. Let q be one of these. Let us lay q off on the A axis. Since q is a limiting point of A, any little interval as J contains an infinity of points of A. Now, however small K is taken, there exist intervals J lying within K which contain an infinity of points of A. Hence K contains an infinity of points of A, and p is a limiting point of A. Thus p lies in A'.

2. The extension of this demonstration to \mathfrak{N}_m is obvious. To show that p lies in A', we have to show that $D_{\epsilon}(p)$ contains an infinity of points of A, however small ϵ is taken. To this end, let $\rho < \epsilon$. Let q be a point of A' in $D_{\rho}(p)$. Then $D_{\sigma}(q)$ contains an infinity of points of A, however small σ is. But if

$$\rho + \sigma < \epsilon$$

 $D_{\sigma}(q)$ lies in $D_{\epsilon}(p)$, by 249. Hence $D_{\epsilon}(p)$ contains an infinity of points of A.

3. We have just shown that A'' lies in A'. It is, however, not necessary that A' lies in A.

Thus, if $A=1, \frac{1}{2}, \frac{1}{3}, \dots, A'=(0)$, and this does not lie in A.

267. Extreme values of a domain. 1. Let the variable x range over a rectilinear domain D which is limited to the right.

We form a partition (A, B) as follows: in A we put all numbers of \Re which are \geq any number in D; in B we put all numbers of \Re which are > any number of D.

Let this partition be generated by μ [130].

We call μ the maximum of x or of D, and write

$$\mu = \text{Max } x = \text{Max } D.$$

The fact that a domain E is not limited to the right may be denoted by $\operatorname{Max} x = \operatorname{Max} E = +\infty,$

where x ranges over E.

2. Let D be limited to the left. We form a partition (A, B) by putting in A all numbers of \Re which are < any number of D,

and in B all numbers which are \equiv any number of D. If the number λ generates this partition, we call λ the minimum of x or of D, and write

$$\lambda = \operatorname{Min} x = \operatorname{Min} D$$

The fact that a domain E is not limited to the left may be denoted by $\min x = \operatorname{Vin} D = -\infty$,

where x ranges over E

Ex 1

$$D = (a \ b) \ a < b$$
 $M | n x = a \ Max x = b$

We note that z takes on both its min mum and maximum values in D

Here z takes on both its maximum and minimum values.

$$\delta \sim x \times M \qquad e = x \times M$$

In Fig. 8 4 z takes on he that its minimum nor its maximum values.

268 1 The maximum and minimum values of x are called its extreme values or extremes

Let e be an extreme of D II the point e is an isolated point of D, e is called an isolated extreme, otherwise e is a non isolated extreme.

Evidently an seolated extreme of D lies in D

2 When, however, e is a non isolated extreme, it may or may not he in D. In this case we have the theorem

If e be a finite non molated extreme of D it is an extreme of D', the first derivative of D

To fix the ideas, let

Since e is not isolated, it is a lumiting point of D, and hence has in D'

Since no z of D is >c. no z of D' is >c Hence

3. We have obviously the following:

Let every x of D be $\geq \mu$, while for each $\epsilon > 0$ there exists in D an $x > \mu - \epsilon$. Then $\mu = \text{Max } D$.

A similar theorem holds for a minimum.

4. Let M be such that

$$\operatorname{Min} x \leq \mathfrak{M} \leq \operatorname{Max} x;$$

we call M a mean value of x, or a mean of x, and write

$$\mathfrak{M} = \operatorname{Mean} x$$
.

269. 1. Let e be an extreme, finite or infinite, of the function $f(x_1 \cdots x_m)$ with respect to a limited domain D. Then there exists a point a, not necessarily in D, such that e is the extreme of f in any vicinity of a, however small.

The demonstration is precisely analogous to that given in 264.

2. If D contains its limiting points, the point a lies in D.

Various Classes of Point Aggregates

270. Each point p of an aggregate A is either an isolated point or a limiting point of A. Let us call A_i the aggregate of the former points and A_{λ} the aggregate of the latter points.

Then

$$A = A_{\iota} + A_{\lambda}$$

If $A_{\lambda} = 0$, then $A = A_{\alpha}$, and A is an isolated aggregate.

If $A_1 = 0$, then $A = A_2$, and A is dense.

A may contain all its limiting points; it is then complete.

If A is dense and complete, it is *perfect*. It then contains all its limiting points, and every point of A is a limiting point.

A point aggregate such that each of its points is an inner point is called a region. Cf. 247.

It is sometimes convenient to consider the aggregate formed of a region and its frontier points. Such an aggregate is called a complete region.

For example, the interior of a circle forms a region. If we add its circumference we get a complete region.

271 Er 1 is an isolated aggregate 4=1444-

Er 2 A=0 1.1 1. . is a complete aggregate

Er 3 A = the rational numbers in a certain interval.

A is dense but not complete

Fr 4 A = the interval (a b) A 13 perfect

Ex 5 A = the interval (a4. b)

A is dense but not con plete

Ex 6 A region is dense but not complete

A completed region is perfect,

Ex. 7 In the interval (0 1) remove the points 0, 1, 1, 1, ...

The remaining points form a regi n.

Ex 8 In the plane %, let

A - a. a.

be an aggregate having a single limiting point e. Let us suppose that a does not he m A About each a let us describe a circle C, of radius so small that no two circles here a point in common. The aggregate formed of the points of Ra within each circle C. is a region P.

The aggregate formed of all the regions I, to also a region

272 1 An interesting example of a rectilinear perfect aggregate lying in an interval 2 and yet not embracing all the points of M is the following, due to Cantor Let

$$a = a_1 a_2 a_3$$

be expressed in the triadic system [144], restricting, however, the numbers a_1, a_n to the values 0, 2 Then A = |a| is such an aggregate, as we now show

We can get a good idea of this aggregate as follows

Let the interval (1, 4) be of unit length. We divide it into three equal segments, (1, 2), (2, 3), (3, 4) The points 1, 3 are points of A No point of A falls within the middle segment (2, 3) We have therefore marked this segment heavy in the figure. We now divide the segments (1, 2) and (3, 4) into three equal segments,

$$(1,5)$$
, $(5,6)$, $(6,2)$, and $(3,7)$, $(7,8)$, $(8,4)$.

The end points 6, 8 are points of A. No point of A falls within the segments (5, 6), (7, 8), which are therefore marked heavy.

In this way we can continue indefinitely subdividing the segments within which a point of A falls. Consider the end points of a heavy interval, say the interval (5, 6). Its right hand end point is obviously a number of A having a finite representation. Its left hand end point is a point of A whose representation is infinite.

To show now that A is perfect, let us begin by showing that every point a of A is a limiting point.

Let

$$a = \cdot a_1 a_2 \cdots a_s$$

be a point having a finite representation [144, 5]. Obviously, a is the limit of the sequence,

$$a' = \cdot a_1 \cdots a_s 2,$$

 $a'' = \cdot a_1 \cdots a_s 02,$
 $a''' = \cdot a_1 \cdots a_s 002,$

Let

$$a = \cdot a_1 a_2 a_3 \cdots$$

be a point whose representation is infinite. It is obviously the limit of the sequence,

$$a' = \cdot a_1,$$

$$a'' = \cdot a_1 a_2,$$

$$a''' = \cdot a_1 a_2 a_3,$$

Hence every point of A is a limiting point. On the other hand A contains all its limiting points.

For every limiting point α of A is either, 1°, an end point of the black intervals, or, 2°, not such a point.

170 FIRST NOTIONS CONCERNING POINT AGGREGATES

In case 1°, α is obviously a point of A. In case 2°, if $\alpha \neq 0$, we can find a monotone sequence of points in A.

$$a' = a_1,$$
 $a'' = a_1a_2,$
 $a''' = a_1a_1a_2,$

whose limit is a

On the other hand, the limit of this sequence is

 $a_1a_2a_3$

which is a number of A Hence a is in AShould a = 0 this method is inapplicable

But obviously a = 0 is in A

2 It is easy to generalize the above example as follows Let

 $a=a_1a_2a_3$ be expressed in an m adic system restricting the numbers a_1,a_2 , to a part of the system

0, 1, 2, m-1,

for example,

CHAPTER VI

LIMITS OF FUNCTIONS

FUNCTIONS OF ONE VARIABLE

Definitions and Elementary Theorems

273. 1. We extend now the notion of limit, by defining limits of functions. We begin by considering functions of a single variable x.

Let f(x) be a one-valued function defined over a domain D. Let

$$A = a_1, \ a_2, \ a_3 \ \cdots \tag{1}$$

be any sequence of points of D, such that

 $\lim a_n = a$; a finite or infinite, $a_n \neq a$.

If the sequence

$$f(a_1), f(a_2), f(a_3) \cdots$$
 (2)

has a limit η , finite or infinite, always the same, however the sequence A be chosen, we say η is the limit of f(x) for x = a and write

$$\eta = \lim_{x=a} f(x),$$

or, more shortly,

$$\eta = \lim f(x).$$

We also say f(x) approaches or converges to η as a limit, when x approaches a as a limit. This may be expressed by the symbol

$$f(x) \doteq \eta$$
.

2. If for some sequence 1) the limit of 2) does not exist, we say the limit of f(x) for x = a does not exist.

3 Since the limit of 2) must be η however the sequences 1) are chosen (provided, of course, they have a as limit and $a_n \neq a$), we have the theorem

Let $A = \{a_n\}$, $B = \{b_n\}$ be two sequences lying in D, let $a_n = a$, $b_n = a$

If
$$\lim f(a_n) \neq \lim f(b_n)$$
,

then $\lim f(x)$, for x = a, does not exist

274 1 It is sometimes convenient to restrict the sequences $A = a_1, a_2$ so that all the points a_n lie to the right of a. In this case we call η a right hand limit and write

$$\eta = \lim_{x \to a} f(x)$$
 or $\eta = f(a+0)$ or $\eta = R \lim_{x \to a} f(x)$ or $\eta = R \lim_{x \to a} f(x)$

If we restrict the sequences A to be to the left of a, we call no left dand limit and write

$$\eta = \lim_{x \to \infty} f(x)$$
 or $\eta = f(a - 0)$ or $\eta = L \lim_{x \to \infty} f(x)$ or $\eta = L \lim_{x \to \infty} f(x)$

Obviously of

(1

then

$$L \lim f(x) = R \lim f(x) = \eta$$
 (2)

Conversely, if 2) holds, 1) does also

2 Right and left hand limits are called unilateral limits. If we do not care to specify on which side of a the limit is taken, we can denote it by

 $U \lim_{x\to a} f(x)$

275 1 When considering mainte limits or limits for $x=\pm\infty$, it is often convenient to suppose the axes terminated to the right and left by two ideal points $+\infty$, or $-\infty$, respectively. We call these the points at infinity

We call the interval $(G_1 + \infty)$ the domain of $+\infty$, and denote it by

$$D_{\phi}(+\infty)$$
 (1)

We call G the norm of $D(+\infty)$

Let A be a point aggregate lying on our axis. Those of its points which fall in 1) we call the vicinity of $+\infty$ for the aggregate A. We denote it by

 $V_6(+\infty)$. (2)

Similar definitions hold for

$$D_c(-\infty)$$
 and $\Gamma_c(-\infty)$. (3)

2. When G increases, the intervals $(G, +\infty)$ or $(G, -\infty)$ are. in a way, diminishing. It is convenient, for uniformity, to say that $D_G(\pm \infty)$, $V_G(\pm \infty)$

are arbitrarily small when G is taken arbitrarily large, positively or negatively, according to the sign of ∞ .

276. Corresponding to the two ideal points $\pm \infty$, we shall introduce two ideal numbers, which we also denote by $\pm \infty$. These numbers are respectively greater, positively or negatively, than any number in \Re . We say they are infinite.

The system formed by joining $\pm \infty$ to the system \Re we denote by $\overline{\Re}$.

We shall perform no arithmetical operations with these ideal numbers.

277. 1. Most of the theorems established in Chapters I. II for sequences may be extended easily to theorems on limits of functions.

For convenience of reference we collect the following. The reader should remember that a theorem relating to limits for a point x = a may be changed at once into one relating to a left or a right hand limit at a.

2. Let
$$\lim_{x \to a} f(x) = \alpha. \lim_{x \to a} g(x) = \beta. \quad \text{a finite or inf.}$$

$$\lim_{x \to a} (f \pm g) = \alpha \pm \beta,$$

$$\lim_{x \to a} fg = \alpha\beta.$$

$$\lim_{x \to a} fg = \alpha\beta.$$

$$\lim_{x \to a} f = \frac{\alpha}{\beta}. \quad \beta \neq 0.$$
See 49, 50, 51, 98.

174 LIMITS OF FUNCTIONS

3 In $V^*(a)$, a finite or infinite let $f(x) \le g(x) \le h(x)$

Let $\lim_{x \to \infty} f(x) = \lim_{x \to \infty} h(x) = \lambda$

Then $\lim_{x \to \infty} q(x) = \lambda$.

See 107

4 Let lim f(x) a finite or enf

be finite If $\lambda < f(x) \le \mu$ on $V^{\bullet}(a)$

then $\lambda \leq \lim f(x) \leq \mu$

See 106 1 5 Let

 $\lim f(x) = a, \lim g(x) = \pm \infty \quad \text{a finite or inf}$

Then $\lim_{x \to \infty} (f \pm g) = \pm \infty$ $\lim_{x \to \infty} \frac{f}{g} = 0$

 $\lim fg = \pm \infty$

See 137

6 Let $\lim f(x) \neq 0 \quad \lim g(x) = 0 \quad \text{a finite or inf}$

If g(x) has one sign in I'*(a)

 $\lim_{x \to +\infty} \frac{f}{g} = \pm \infty$

See 137

7 In Va(a) a finite or infinite let

 $f(x) \ge g(x)$ If

 $\lim_{z \to \infty} g(z) = +\infty,$

 $\lim f(x) = +\infty$

See 138

8. In $V^*(a)$ let f(x) be limited and monotone. Then

$$f(a+0), \quad f(a-0)$$

exist and are finite.

See 109.

Second Definition of a Limit

278. 1. If

$$\lim_{x=a} f(x) = \eta, \quad a \text{ finite or inf.}$$

there exists for each $\epsilon > 0$ a vicinity $V^*(a)$ such that

$$|\eta - f(x)| < \epsilon \tag{1}$$

in V*(a).

For let D be the domain of definition of f(x). Let $\Delta = \{\xi\}$ be the points of D, if any such exist, for which 1) is not satisfied. Let us suppose at first that a is finite. Let

$$\min |\xi - \alpha| = \mu.$$

If $\mu > 0$, let $0 < \delta < \mu$, then 1) holds in $V_{\delta}^*(\alpha)$.

If $\mu = 0$, let

be a sequence in Δ , whose limit is a. Then

$$\lim_{n\to\infty}f(\xi_n)\neq\eta,$$

and this contradicts the hypothesis.

Thus, when a is finite, there exists always a vicinity $V_{\delta}^*(a)$ for which 1) holds.

Suppose $a = +\infty$. Let

Max
$$\xi = \mu$$
.

If μ is finite, let $G > \mu$. Then 1) holds in $V_G(+\infty)$.

If $\mu = +\infty$, let

be a sequence in Δ whose limit is $+\infty$. Then

$$\lim f(\xi_n) \neq \eta,$$

and this contradicts the hypothesis.

A similar reasoning applies when $a = -\infty$.

2. We wish expressly to note that in passing to the limit x = a, the variable x never takes on the value x = a.

279 The converse of the theorem 278 is obviously true viz If for each $\epsilon > 0$ there exists a vicinity $V_{\epsilon}^{\bullet}(a)$ $\delta > 0$, a finite of infinite such that

 $|\eta - f(x)| < \epsilon$ in V.*(a) then

 $\ln n f(x) = \eta$

280 1 From 278 and 279 we see that we can take the follow ing as definitions of a limit

The limit of f(x) for x = a is q when for each $\epsilon > 0$ there exists aδ > 0 such that $|f(x)-n|<\epsilon$ (1

$$|f(x)-\eta|<\epsilon$$
in $I_4^*(a)$

This condition we shall express as follows

$$\epsilon > 0$$
 $\delta > 0$ $|f(x) - \eta| < \epsilon V_{\epsilon}^{*}(a)$ (2)

Such a line of symbols is to be read as above

2 The limit of f(x) for $x = +\infty$ is η when for each $\epsilon > 0$ there exists a G>0 such that 1) lolds in Va(+\infty)

This condition we shall express thus

$$\epsilon > 0$$
, $G > 0$ $f(x) - \eta | < \epsilon$ $V_a(+\infty)$

8 The limit of f(x) for $x = -\infty$ is η when for each $\epsilon > 0$, there exists a G < 0 such that 1) holds in Vo(- 00)

This condition we shall express thus

$$\epsilon > 0$$
 $G < 0$, $|f(x) - \eta| < \epsilon$ $V_q(-\infty)$

281 1 If

in V*(a)

 $\lim f(x) = +\infty \qquad \text{a finite or infinite}$

there exists for each G > 0 a memity V*(a) such that f(x) > G1

For let $\Delta = \{\xi\}$ be the points of D, if any such exist, for which 1) does not hold

1°. Let a be finite. Let

$$\min |\xi - a| = \mu.$$

If $\mu > 0$, let $0 < \delta < \mu$. Then 1) holds in $V_{\delta}^*(\alpha)$.

If $\mu = 0$, let

$$\xi_1, \ \xi_2, \ \cdots$$

be a sequence in Δ whose limit is a. Then

$$\lim f(\xi_n) \neq +\infty$$
;

and this contradicts the hypothesis.

2°. Let $a = +\infty$. Let

$$\operatorname{Max} \xi = \mu.$$

If μ is finite, let $G > \mu$; then 1) holds in $V_{\theta}(+\infty)$.

If μ is infinite, let

$$\xi_1, \ \xi_2, \ \cdots$$

be a sequence in Δ whose limit is $+\infty$. Then

$$\lim f(\xi_n) \neq +\infty;$$

and this contradicts the hypothesis.

A similar reasoning holds when $a = -\infty$.

The reader will observe that this demonstration is analogous to that of 278.

2. The converse of 1) is obviously true, viz.:

If for each G > 0, there exists a vicinity $V^*(a)$, a finite or infinite, such that

f(x) > G

in V*(a), then

$$\lim_{x=a} f(x) = +\infty.$$

282. 1. From 281 we see that the following definitions of limits may be taken:

$$\lim_{x=a} f(x) = +\infty, \text{ if }$$

$$M > 0$$
, $\delta > 0$, $f(x) > M$, $V_{\delta}^*(a)$,

which in full means: if for each M>0, large at pleasure, there exists a $\delta>0$, such that f(x)>M in $V_{\delta}^*(a)$.

$$\lim_{x\to\infty}f(x)=-\infty, \text{ if }$$

$$M < 0, \delta > 0, f(x) < M, V_{i}^{\bullet}(a)$$

) ϵ if for each M < 0 there exists a $\delta > 0$ such that f(x) < M in $V_1^\bullet(a)$

$$\lim_{x\to\infty} f(x) = +\infty, \text{ if}$$

$$M>0, \quad G>0, \quad f(x)>M, \quad V_0(+\infty).$$

4.
$$\lim_{x \to +\infty} f(x) = -\infty, \text{ if }$$

$$M < 0$$
 $G > 0$, $f(x) < M$, $V_o(+\infty)$.

5.
$$\lim_{x \to \infty} f(x) = +\infty, \text{ if }$$

$$M > 0$$
, $G < 0$, $f(x) > M$, $V_{\phi}(-\infty)$

$$\lim_{n \to \infty} f(x) = -\infty,$$

$$M<0, \quad G<0, \quad f(x)< M, \quad V_\phi(-\infty)$$

7. The limit, finite or infinite, of f(x) for $x = +\infty$ or $-\infty$ may be represented by $f(+\infty)$, $f(-\infty)$.

respectively

283 By the aid of the ideal points, with their associate domains and vicinities, we may sum up all the preceding six cases in one general statement

 $\eta = \lim f(x)$ a, η finite or infinite,

when, $D(\eta)$ bring taken small at pleasure, there exists a vicinity $V^{\bullet}(a)$, such that f(x) lies in $D(\eta)$ when x runs over $V^{\bullet}(a)$

See 275, 2

The reader should observe that the two demonstrations of 218 and 281 are perfectly parallel. It is easy, by employing the convention of 275, 2, to formulate the demonstration given in 218 so as to include the cases treated in 281, and so make the latter unnecessary.

284. In order that $\lim_{x \to a} f(x)$ exists, a finite or infinite, it is necessary and sufficient that for each $\epsilon > 0$ there exists a vicinity $V^*(a)$, such that

 $|f(x_1) - f(x_2)| < \epsilon, \tag{1}$

for any pair of points x_1, x_2 in $V^*(a)$.

It is necessary. For, if

$$\eta = \lim_{x=a} f(x),$$

then for each $\epsilon > 0$ there exists a $V^*(a)$, such that

$$|\eta - f(x)| < \frac{\epsilon}{2}$$

for any x in $V^*(a)$. Let x_1 , x_2 be two points in $V^*(a)$. Then

$$|\eta - f(x_1)| < \frac{\epsilon}{2}, \quad |\eta - f(x_2)| < \frac{\epsilon}{2}.$$

Adding these two inequalities, we get 1).

It is sufficient. For, let a_1, a_2, \dots be a sequence of points in $V^*(a)$, having a as limit. Then the sequence

$$f(a_1), f(a_2), \dots$$

is regular by 1). It therefore has a limit η .

Then

$$\epsilon > 0$$
, m' , $|\eta - f(a_n)| < \frac{\epsilon}{2}$ $n > m'$. (2)

Let $B = b_1$, b_2 , ... be any sequence of points in $V^*(a)$ whose limit is a. Then, by 1),

$$|f(a_n)-f(b_n)| < \frac{\epsilon}{2}, \quad n > m''.$$
 (3)

Adding 2), 3), we have

$$|\eta - f(b_n)| < \epsilon$$
. $n > m$, $m > m'$, m'' . (4)

But since B was an arbitrary sequence, the relation 4) states that

$$\eta = \lim_{x \to x} f(x).$$

Graphical Representation of Limits

285 The graphical representation of limits of sequences explained in 43, 44, and 124 may be readily extended to limits of functions

Let the graph of f(x) be referred to rectangular coordinates Let D be the domain of f(x), and let

 $\lim f(x) = l$

Then the condition

$$\epsilon > 0$$
 $\delta > 0$, $|f(x)-l| \le \epsilon$ $V_1^{\epsilon}(a)$,

has the following geometric interpretation

About the line y = l construct a band (shaded in the figure) of width 2 e e being small at pleasure. Then there exists corre sponding to this an interval of extent 28 (marked heavy in the figure) such that f(x)

Arrestard mit at gaille? A to a + x does tot bard s sitt at elle? In general, as a is made smaller and smaller, & becomes smaller and smaller But for each e band, however small, there corre sponds a 8 interval of length >0

$$\lim f(x) = +\infty$$

Draw the line y = M where M > 0 is large at pleasure Then there exists, corresponding to this M & Sinterval marked he is in the figure, such that f(x) falls in the M band (shaded in the figure) for each x +a of D. falling in the 8 interval

As M is taken greater and greater, the corresponding & interval becomes in general, smaller and smaller But for each M, bowever large, there corresponds a & interval of length > 0

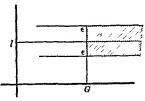

287 Let

$$\lim f(x) = l$$

Draw the line y = l, and construct an ϵ -band, as in figure. For each ϵ there exists a G > 0, such that

f(x) falls in the ϵ -band for each x of D, falling in the interval $(G, +\infty)$.

These examples will suffice to illustrate the graphical interpretations of limits, when f(x) is plotted in rectangular coördinates.

288. 1. When the graph of y = f(x) is given by means of two axes, as explained in 191, the geometric interpretation of limits of f(x) will be made clear by the following:

Let
$$\lim_{x \to a} f(x) = l$$
. (1 $\int_{y} f(x) dx = l$)

About y=l we mark off the ϵ -interval; about x=a we mark off the δ -interval.

Then 1) requires that f(x) falls in the ϵ -interval for each value of $x \neq a$ in D, falling in the δ -interval.

2. Let
$$\lim_{x \to \infty} f(x) = +\infty.$$

On the y-axis we mark off at pleasure the point M>0. Then for each M there exists a δ -interval, such that f(x) falls in the interval $(M, +\infty)$, for each $x \neq a$ of D falling in the δ -interval.

289. Let
$$\lim_{x \to a} f(x) = l. \qquad l \text{ finite or infinite.}$$

$$x = a + bu, \qquad b \neq 0, \tag{1}$$

then

$$\lim_{u=0} f(x) = l. \tag{2}$$

For, while x ranges over the domain D on the x-axis, u ranges over a domain Δ on the u-axis.

The two axes x and u stand in 1 to 1 correspondence by virtue of 1). To the point x=a on the x-axis corresponds the point u=0 on the u-axis.

$$f(x) = f(a+bu) = \phi(u).$$

Then if x and u are corresponding points, f has the same value at z as d has at u To fix the ideas let I be finite From

$$\epsilon > 0, \ \delta > 0, \ l - f(x) | < \epsilon, \ \text{in} \ V_{\delta}^{\bullet}(a),$$

follows where $\delta_1 = \frac{1}{r} \delta$

$$|1-\phi(u)|<\epsilon$$
, in $Y_{a_i}^{a_i}(0)$,

But from 3), 4) follows 2)

290 1 Let

$$\lim_{x\to a} f(x) = l \qquad l \text{ finite or infinite,}$$

(3

(4

Let

$$x = \frac{1}{u}$$

Then

$$R \lim_{x \to 0} f(x) = l$$
, and conversely

This follows at once, as in 289. by observing that to points in the 0 40 shaded interval on the g axis correspond points in the shaded interval on the waxis

2 Let

$$\lim_{x\to\infty} f(x) = 1 \qquad \text{I finite or infinite.}$$

Let

$$x=\frac{-1}{u}$$

Then

$$R \lim_{x \to a} f(x) = L$$

and convertely

291 1 As a result of 289 and 290, we may, by the aid of the transformations.

transform

$$u = \alpha x + \beta$$
, and $u = \frac{1}{x}$

Rlim into Rlim Llim, or lim

Similarly,

$$\lim_{x=\pm\infty} \text{ into } R \lim_{y=a} \text{ or } L \lim_{y=a}$$

2. In particular, any limit x = a or $\pm \infty$ may be transformed into one with respect to x = 0.

292. Let $u = \phi(x)$, and

$$\lim u = b. \qquad a, b \text{ finite or infinite.} \qquad (1)$$

Let y = f(u), and

$$\lim_{n \to \infty} y = \eta. \qquad \eta \text{ finite or infinite.} \qquad (2)$$

Then if $\phi(x) \neq b$ in $V^*(a)$,

$$\lim_{\eta \to 0} y = \eta. \tag{3}$$

To fix the ideas, suppose a, b, η are finite. Then since 2) holds,

$$\epsilon > 0$$
, $\sigma > 0$, $|y - \eta| < \epsilon$, $V_{\sigma}^*(b)$.

But, by 1),

$$\sigma > 0$$
, $\delta > 0$, $0 < |u - b| < \sigma$, $V_{\delta}^*(a)$.

Hence while x ranges over $V_{\delta}^*(a)$, y lies in $D_{\epsilon}(\eta)$. Thus

$$\epsilon > 0$$
, $\delta > 0$, $|y - \eta| < \epsilon$, $V_{\delta}^*(a)$.

But then 3) holds.

The case that any or all the symbols a, b, η are infinite is perfectly analogous.

293. Let $u = \phi(x)$, and

$$\lim u = b$$
. a finite or infinite.

Let y = f(u), and

$$\lim y = \eta.$$

If $f(b) = \eta$, then

$$\lim y = \eta.$$

This follows as in 292.

294 1 Let y=f(x) be a universant function in a unilateral vicinity V* of a If [274, 2] $U \lim y = \delta$,

$$y = \delta, [274,$$

then

$$U \lim x = a$$

To fix the ideas, suppose y is increasing in the left hand vicinity of a

Let \$>0 be arbitrarily small, and a - c - d < a

$$\delta - \delta > y'$$

Then, while y remains in $LV_{\bullet}^{\bullet}(b)$ x remains in $LD_{\bullet}(a)$

2 Let y = f(x) be univariant in Vo(a), where a is a bilateral limiting point of V. If $\lim y = \delta$.

then

The demonstration is analogous to that of 1

Examples of Lamits of Functions

295 1

For, however small $\epsilon > 0$ is taken, there exists an arc $\delta > 0$ such that

$$|z| < \epsilon$$
 $|z| < \delta$

 $\lim \cos x = 1$

For, however small $\epsilon > 0$ is taken, there exists an arc $\delta > 0$ such that

$$1 - \cos x < \epsilon$$
 $|x| < \delta$

(2

296. 1.
$$\lim_{x=a} \sin x = \sin a$$
. (1

For, let

x = a + u.

Then

 $\sin x = \sin (a + u) = \sin a \cos u + \cos a \sin u.$

Since

 $\lim_{x \to a} \sin x = \lim_{x \to 0} \sin (a + u),$

and

 $\lim_{u=0} \sin u = 0$, $\lim_{u=0} \cos u = 1$,

equation 2) gives, on passing to the limit, 1), by 289.

2. Similarly,

 $\lim_{x \to a} \cos x = \cos a.$

297. 1.
$$L \lim_{x=\pi/2} \tan x = +\infty$$
. (1)

For, in $LV^*(\pi/2)$, $\tan x > 0$.

As

$$\tan x = \frac{\sin x}{\cos x}$$

and

$$\lim_{x \to \pi/2} \sin x = 1$$
, $\lim_{x \to \pi/2} \cos x = 0$,

we have 1), by 277, 6.

2. Similarly,

$$R\lim_{x=\pi/2}\tan x=-\infty.$$

298. 1.

$$\lim_{r\to 0}e^r=1.$$

This follows at once from 172.

$$\lim_{x=a} e^x = e^a.$$

For, let

$$x = a + u$$
.

Then, by 289,

$$\lim_{x=a} e^x = \lim_{u=0} e^{a+u} = e^a \lim_{u=0} e^u$$
$$= e^a, \text{ by 1.}$$

4 For, let

5 Obviously as in 1 2

This follows directly from 171 2 In Vo(a) let f(x) > 0 Let

This follows at once from 178

3

Æ

299 1 Let Then

Then

300 1

 $x \simeq \frac{-1}{y}$

Then

 $\lim_{n\to\infty} e^x = R \lim_{n\to\infty} \frac{1}{\epsilon^n} \text{ by } 290 - 2$

This follows at once from 169

 $\lim a^r = a^r$ $f(x) = \frac{e^t - 1}{e^t + 1}$

 $R\lim_{x\to a} f(x) = +1 \qquad L\lim_{x\to a} f(x) = -1$

 $\lim_{x\to x} (f(x))^x = \eta^x$

 $\lim_{x\to x} f(x) = 0$

 $\lim_{x\to a} (f(x))^{\mu} = 0$ = 1

 $=+\infty$ $\mu<0$

 $\lim \log x = \log a \quad a > 0$

= 0 by 277, 5

$$\lim_{a \to +\infty} \log x = +\infty.$$

This follows at once from 179.

3.
$$R \lim_{x=0} \log x = -\infty.$$
 For, set
$$x = \frac{1}{x}.$$

Then

$$R \lim_{x \to 0} \log x = \lim_{u \to \infty} \log \frac{1}{u} = -\lim_{u \to \infty} \log u = -\infty.$$

4. Let

$$\lim_{x=a} f(x) = \eta > 0.$$

Then

$$\lim_{x=a} \log f(x) = \log \eta = \log \lim_{x=a} f(x).$$

This follows at once from 178.

301. 1.
$$\lim_{x \to 0} \frac{\sin x}{x} = 1.$$

From geometry, we have

Hence, for $0 < x < \pi/2$,

$$\frac{1}{2}\sin x\cos x < \frac{1}{2}x < \frac{1}{2}\tan x;$$

or

$$\cos x < \frac{x}{\sin x} < \frac{1}{\cos x}$$

 \mathbf{As}

$$R\lim_{x=0}\cos x=R\lim_{x=0}\frac{1}{\cos x}=1,$$

we have, by 277, 3,

$$R \lim_{x=0} \frac{x}{\sin x} = 1. \tag{1}$$

Set in 1),

$$x = -u$$
.

Then
$$R \lim_{x=0} \frac{x}{\sin x} = L \lim_{u=0} \frac{u}{\sin u} = 1.$$
 (2)

Whence, by 277 2 $\lim_{x \to \infty} \frac{\sin x}{x} = 1$

2 From 1 we have readily

 $\lim_{h \to 0} \frac{\sin ax}{h} = \frac{a}{h} \qquad b \neq 0$

For. $\frac{\sin ax}{\lambda x} = \frac{a}{\lambda} \frac{\sin ax}{ax}$

= a sin u,

setting w= ar

 $\lim_{x \to 0} \frac{\tan x}{x} = 1$ 302 For.

tanz sinz 1

But

 $\lim_{x \to \infty} \frac{\sin x}{x} = 1 \lim_{x \to \infty} \frac{1}{x} = 1$

Thus, passing to the limit in 2) we get 1) by 277, 2

 $\lim \frac{\sin (x+h) - \sin x}{1} = \cos x$ 303

For. $\frac{\sin(x+h) - \sin x}{h} = \frac{2\cos(x+\frac{1}{2}h)\sin\frac{1}{2}h}{h}$

Also

 $\lim_{x \to a} \cos(x + \frac{1}{2}h) = \cos x,$ $\lim_{h\to\infty}\frac{2\sin\frac{1}{h}h}{h}=\lim_{h\to\infty}\frac{\sin\frac{1}{h}h}{h}=1$

Passing to the limit in 2) we get 1)

(2

(1

(2

For,
$$\lim_{x \to 0} \frac{1 - \cos x}{x^2} = \frac{1}{2}.$$
 (1)
$$\frac{1 - \cos x}{x^2} = \frac{2 \sin^2 \frac{1}{2} x}{x^2} = \frac{1}{2} \left(\frac{\sin \frac{1}{2} x}{\frac{1}{2} x}\right)^2.$$

$$\lim_{x \to 0} \frac{\tan x - \sin x}{x^3} = \frac{1}{2}.$$
For,

for,
$$\frac{\tan x - \sin x}{x^3} = \frac{\tan x}{x} \cdot \frac{1 - \cos x}{x^2}.$$

305. 1.
$$\lim_{x \to +\infty} e^{-x} \cos x = 0.$$
 (1)

Here
$$\lim e^{-x} = 0$$
, by 298, 4,

while $\lim \cos x$

does not exist. We cannot, therefore, apply the theorem 277, 2, that the limit of the product is the product of the limits.

We therefore proceed thus:

$$-e^{-x} \le e^{-x} \cos x \le e^{-x}.$$

Apply now 277, 3. This gives 1).

2. We may see the truth of 1) geometrically.

Let

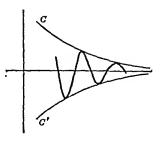

$$y_1 = e^{-x}, \ y_2 = \cos x,$$

and

$$y = e^{-x} \cos x = y_1 y_2.$$

Let us draw the graphs C, C' of $\pm y_1$. To get y, we multiply y_1 by the factor y_2 , which takes on all values between -1 and +1. Thus y oscillates between the curves C, C'.

As C, C' approach nearer and nearer the x-axis, the amplitude of the oscillations converges to 0.

The Limit e and Related Limits

306 1 We saw in 119 that

$$\lim_{n \to \infty} \left(1 + \frac{1}{n}\right)^n = e \qquad n = 1, 2, 3, \dots \tag{1}$$

Let us consider now the more general limit

$$\lim_{x\to\infty} \left(1+\frac{1}{x}\right)^x$$

I tch x will be between two integers n + 1, or

$$n < x < n + 1$$

Then

$$1 + \frac{1}{n} \ge 1 + \frac{1}{r} > 1 + \frac{1}{n+1}$$

and

$$\left(1 + \frac{1}{n}\right)^{n-1} > \left(1 + \frac{1}{x}\right)^{n} > \left(1 + \frac{1}{n+1}\right)^{n}$$

Rut

$$\left(1+\frac{1}{n}\right)^{n+1} = \left(1+\frac{1}{n}\right)\left(1+\frac{1}{n}\right)^n,$$
 (3)

und

$$\left(1 + \frac{1}{n+1}\right)^n = \left(1 + \frac{1}{n+1}\right)^{n+1} = \frac{1}{1 + \frac{1}{n+1}}.$$
 (4)

Thus 3), 4) give in 2),

$$\left(1 + \frac{1}{n}\right)\left(1 + \frac{1}{n}\right)^{n} > \left(1 + \frac{1}{x}\right)^{n} > \left(1 + \frac{1}{n+1}\right)^{n+1} \frac{1}{1 + \frac{1}{n+1}}$$
 (5)

\ow, by 1),

$$\lim \left(1+\frac{1}{n}\right)^n = \lim \left(1+\frac{1}{n+1}\right)^{n+1}.$$

Also,

$$\lim_{n \to \infty} \left(1 + \frac{1}{n}\right) = \lim_{n \to \infty} \frac{1}{1 + \frac{1}{n-1}} = 1.$$

Hence 5) gives

$$\lim_{x \to \infty} \left(1 + \frac{1}{x}\right)^x = \varepsilon$$

$$\lim_{x \to -\infty} \left(1 + \frac{1}{x}\right)^x = e. \tag{1}$$

For, let

$$x = -u$$
.

Then

$$\left(1 + \frac{1}{x}\right)^x = \left(1 - \frac{1}{u}\right)^{-u} = \left(1 + \frac{1}{u - 1}\right)^u$$

$$= \left(1 + \frac{1}{v}\right)\left(1 + \frac{1}{v}\right)^v,$$
(2)

where

$$y - 1 = v$$
.

But, when $x \doteq -\infty$, $u \doteq +\infty$, and hence $v \doteq +\infty$.

As

$$\lim_{r \to +\infty} \left(1 + \frac{1}{v} \right) = 1, \quad \lim_{r \to +\infty} \left(1 + \frac{1}{v} \right)^r = e,$$

we get 1), on passing to the limit in 2).

308. From

$$\lim_{x \to +\infty} \left(1 + \frac{1}{x}\right)^x = e,$$

we get, setting

$$x=\frac{1}{u}$$

$$R \lim_{u=0} (1+u)^{\frac{1}{u}} = e. \tag{1}$$

From

$$\lim_{x \to -\infty} \left(1 + \frac{1}{x} \right)^x = e,$$

we get, setting

$$x=\frac{1}{v}$$

$$L \lim_{u=0} (1+u)^{\frac{1}{u}} = \epsilon.$$
 (2)

From 1), 2) we have

$$\lim_{x \to 0} (1+x)^{\frac{1}{x}} = e. \tag{3}$$

192 LIMITS OF FUNCTIONS 309

lm (1+24) = e.

For. $y = (1 + ux)^{\frac{1}{u}} = \{(1 + ux)^{\frac{1}{ux}}\}_{x \in \mathbb{R}^n}$

= 1(1+0) 1=

where

Rnt $\lim_{t\to\infty} (1+v)^{\frac{1}{2}} = \epsilon$

Hence, by 299, $\lim y = e^{\epsilon}.$

316 $\lim_{z \to \infty} \frac{\log(1+z)}{z} = 1.$ For,

 $\lim_{x \to \infty} \frac{\log(1+x)}{x} = \lim_{x \to \infty} \log(1+x)^{\frac{1}{2}}$ $= \log \lim_{x \to 0} (1+z)^{\frac{1}{x}}$, by 800, 4)

= log e, by 308, 3)

(1

= 1

 $\lim_{n \to \infty} \frac{a^{n}-1}{n} = \log a \qquad a > 0.$ 311 (1

Set Then

 $\lim_{n\to\infty}u=0,$

by 298, 5. Then, by 292,

 $\lim_{n \to \infty} \frac{\log(1+u)}{a} = \lim_{n \to \infty} \frac{\log a^{n}}{a^{n}-1}$ (2

=1, by 210. But

 $\log a^* = x \log a$.

This in 2) gives 1)

$$\lim_{x \to 0} \frac{(1+x)^{\mu} - 1}{x} = \mu. \tag{1}$$

From 310 we have

$$\lim_{u=0} \frac{\log(1+u)}{u} = 1.$$
 (2)

Let

$$u = (1+x)^{\mu} - 1.$$
 $\mu \neq 0.$

Then, by 299,

$$\lim_{n\to\infty}u=0.$$

Hence, by 292, we get from 2)

$$\lim_{x\to 0}\frac{\log(1+x)^{\mu}}{(1+x)^{\mu}-1}=1,$$

or

$$\lim \frac{(1+x)^{\mu}-1}{\log(1+x)} = \mu, \tag{3}$$

since

$$\log(1+x)^{\mu} = \mu \log(1+x).$$

But, by 310,

$$\lim \frac{x}{\log(1+x)} = 1. \tag{4}$$

Now

$$\frac{(1+x)^{\mu}-1}{\log(1+x)} = \frac{(1+x)^{\mu}-1}{x} \cdot \frac{x}{\log(1+x)}$$

Passing to the limit and using 4), we get 1) for the case that $\mu \neq 0$. The case that $\mu = 0$ is self-evident.

FUNCTIONS OF SEVERAL VARIABLES

Definitions and Elementary Theorems

313. For the sake of clearness, we have treated first the limits of functions of a single variable. We consider now the limits of functions in m variables. The extension of the definitions and results of the preceding sections is, for the most part, so obvious that we shall not need to enter into much detail. Should the reader have trouble with the case of general m, let him first suppose m=2 or 3, when he can use his geometric intuition as a guide.

314 In the case of a single variable, we have seen how useful the ideal points to proved In the treatment of limits of func tions of several viriables we shall find it extremely advantageous to adjoin an infinity of ideal points to Ma as follows

Let $A = a_1, a_2, a_3$ be an infinite sequence of points in \Re . Let

 $a_{\bullet} = (a_{\bullet}^{I}, a_{\bullet}^{I}, \cdot a_{\bullet}^{(n)})$ Let

 $\lim a_s' = a_p$ $\lim a_s^{(n)} = a_n$; an an finite or infinite

We say the limit of the sequence A is

 $\alpha = (\alpha, \alpha_{-}),$ a

and write $\alpha = \lim \sigma_{\mathbf{a}}$

If any of the coordinates of a are infinite, we say a is an infinite point. This fact may be briefly denoted by

$$\alpha = \infty$$
,

the symbol on being without sign

There is no point in R. corresponding to an infinite a We therefore introduce an infinite system of ideal points, one for each complex, in which one at least of the symbols, are is ± x Such ideal points

$$a_1, a_2, a_m$$
 (2)

we represent also by 1), and call the m symbols, 2), their coordinates If we employ the graphical representation of 231, we suppose, according to 275, that each axis is terminated

by the ideal points + on and - on Thus, any couplex of se points, one on each axis, such that at least one of these m points is an ideal point, is the representation

of an ideal point in 98. The system of points, formed of \$2, and the ideal points, we denote by 32.

These ideal points are also called points at infinity

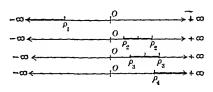

315. 1. The domain of an ideal point $a = (a_1 \cdots a_m)$ is the aggregate of points $x = (x_1 \cdots x_m)$, whose coördinates lie respectively in the domains

 $D_{\rho_1}(a_1), \cdots D_{\rho_m}(a_m).$

It may be represented by $D_{\rho_1 \cdots \rho_m}(a)$.

EXAMPLE. Let m=4, and $a=(-\infty, 1, 2, +\infty)$. The domains in which the coördinates x_1 , x_2 , x_3 , x_4 range, are marked heavy in the figure.

Here ρ_1 is an arbitrarily large negative number; ρ_2 and ρ_3 are arbitrarily small positive numbers; ρ_4 is an arbitrarily large positive number.

2. The points of an aggregate A, which lie in $D_{\rho_1 \cdots \rho_m}(a)$, a being a point at infinity, form the vicinity of a, for that aggregate. We represent it by $V_{\alpha_1 \cdots \alpha_m}(a).$

316. 1. Let $y = f(x_1 \cdots x_n)$ be defined over a domain D. Let $A = a_1, a_2, \cdots$ be a sequence of points in D, and let

 $\lim a_n = \alpha. \qquad \text{a finite or infinite.}$

 $\lim_{n\to\infty} f(a_n) = \eta, \qquad \eta \text{ finite or infinite.}$

is always the same however A be chosen, α remaining fixed and $a_n \neq \alpha$, we say η is the limit of y for $x = \alpha$; and write

$$\eta = \lim_{x_1 = a_1 \cdots x_m = a_m} f(x_1 \cdots x_m),$$

or, more briefly,

$$\eta = \lim_{m \to \infty} f(x_1 \cdots x_m), \text{ or } \eta = \lim_{m \to \infty} f(x);$$

or,

If

$$f(x_1 \cdots x_m) \doteq \eta$$
, or $f(x) \doteq \eta$.

2. Just as in the case of a single variable, we can show that this definition is equivalent to the following:

$$\eta = \lim_{x \to a} f(x_1 \cdots x_m), \quad \eta \text{ finite or inf.}$$

when, taking $D(\eta)$ arbitrarily small, there exists a vicinity $V^*(\alpha)$, such that y remains in $D(\eta)$ when x is in $V^*(\alpha)$. See 278-283.

317 1 The theorems of 277 and 284 hold for functions of several variables as well as for a single variable

2 The generalized theorem of 292 may be stated thus

Let
$$u_1 = \phi_1(x_1 \quad x_n)$$
 $u_n = \phi_n(x_1 \quad x_n)$, and $\lim u_1 = \delta_1 \quad \lim u_n = \delta_n$

Let $y = f(u_1 \quad u_n),$ and

 $\lim y = \eta$

Let u + b in V * (a) Then

$$\lim y = \eta$$

Here a b n may be finite or infinite

The demonstration is perfectly analogous to that in 292

A Method for Determining the Non Existence of a Limit

318 To determine whether

$$\eta = \lim_{n \to \infty} f(x_1 - x_n),$$
 a, η finite or \inf

even exists is often a difficult matter The following simple con sideration analogous to 2"8 2 3 will sometimes show very easily that n does not exist Let W be some partial vicinity of a exclud ing a We may denote the limit, when it exists, of f(z, z,) for z = a when z is restricted to W by

$$\zeta = \lim f(x_1 \quad x_n)$$

Then I must exist, finite or infinite, and however W is taken, we must have

Thus, in case & does not exist, or is different for different W a we know that n does not exact

$$f(x,y) = \frac{xy}{x^2 + y^2}$$

We ask, does

exist? As partial vicinity of the origin, take points on a line

 L_{i}

$$y = ax$$
. $x \neq 0$.

$$\lim_{L} f(x, y) = \lim_{x = 0} \frac{ax^2}{x^2(1 + a^2)} = \frac{a}{1 + a^2}$$

which varies with a; i.e. with L.

Hence the limit in question does not exist.

320. Ex. 2.

$$f(x,y) = \frac{xy^2}{x^2 + y^4}$$

Does

$$\lim_{x,y=0}f$$

exist?

If we take as partial vicinity of the origin points on the line

L; we get

$$\lim_{L} f(x, y) = \lim_{x \to 0} x \cdot \frac{a^2}{1 + a^4 x^2} = 0.$$
 (2)

Thus, however L is chosen, the limit 2) is always the same. We cannot, however, infer that the limit 1) exists, since our method only shows the non-existence of the limit.

Instead of the family of right lines L, let us take a family of parabolas

P;

$$y^2 = ax.$$

Then

$$\lim_{P} f(x, y) = \lim_{x \to 0} \frac{ax^2}{x^2(1 + a^2)} = \frac{a}{1 + a^2},$$

which varies with the particular parabola chosen.

Hence the limit 1) does not exist.

∫321. Ex. 3.

$$f(x, y) = \log \frac{a - x}{a - y}$$
 $x, y < a$

Does

exist?

Let x, y lie on the line

L;

$$a-x=\lambda(a-y).$$
 $\lambda>0.$

Then

$$f(x, y) = \log \lambda$$
.

Hence

$$\lim f(x,y) = \log \lambda,$$

which varies with λ

Recoted Lamits

322 1 Let $f(x_1 x_n)$ be defined over some domain D, and let $a = (a_1 a_n)$

Then

$$\lim f(x_1 - x_n) = f_{i_1}$$

will be in general a function of all the variables except x_{ij} . Also

$$\lim_{x\to a} f_i = f_{i_1,i} = \lim_{x\to a} \lim_{x\to a} f(x_1 - x_n)$$

will be in general a function of all the variables except x_n , x_n . Continuing, we strive at

$$\lim_{t_1=t_2} \lim_{x_1=t_3} \lim_{x_2=t_3} \lim_{x_3=t_3} f(x_1 - x_{st}), \quad s \lesssim m, \quad (1)$$

which is in general a function of all the m variables except

 $x_{i_1}, x_{i_2} = x_{i_2}$ Limits of the type 1) are called iterated limits

Limits of the type 1) are called iterated limits.

In 1) we pass to the limit first with respect to x_n , then with respect to x_n , etc.

A change in the order of passing may produce a change in the final result

2 Iterated limits occur constantly in the calculus, for example, in printial differentiation, differentiation under this integral sign, double integrals, improper integrals, and double series. The treatment of these subjects by the older writers on the calculus is faulty, as we shall see, because they change the order of passing to the limit, without a careful consideration of the correctness of such a step.

323 Ex. 1

$$\lim_{y\to 0}\lim_{z\to 0}\frac{x-y}{x+y}=\lim_{y\to 0}\left(\frac{-y}{y}\right)=-1.$$

$$\lim_{x\to 0}\lim_{x\to 0}\frac{x-y}{x+y}=\lim_{x\to 0}\left(\frac{x}{x}\right)=+1.$$

The two hauts are thus different.

Ex. 2 tim lim

The two limits are thus different.

324. The following is a ease where a change in the order of passing to the limit does not change the result.

$$\lim_{x=a, y=b} f(x, y) = \eta, \qquad \eta \text{ finite or inf.}$$
 (1)

$$\lim_{y=b} f(x, y) = g(x), \quad \text{for } 0 < |x-a| \le \sigma.$$
 (2)

$$\lim_{x \to \infty} f(x, y) = h(y), \quad \text{for } 0 < |y - b| \le \sigma.$$
 (3)

Then

$$\lim_{x \to \infty} g(x) = \lim_{x \to \infty} h(y) = \eta. \tag{4}$$

Let η be finite. From 1) we have

$$\eta - \epsilon < f(x, y) < \eta + \epsilon$$
, in $V_{\delta}^*(a, b)$.

In this relation, pass to the limit x = a; then

$$\eta - \epsilon \le g(x) \le \eta + \epsilon$$
, for $0 < |x - a| < \delta$.

Henee

$$\lim g(x) = \eta.$$
(5)

Similarly,

$$\lim h(y) = \eta. ag{6}$$

From 5), 6) we have 4).

Let $\eta = +\infty$. Then from 1)

$$f(x, y) > G$$
, in $V_{\delta}^*(a, b)$.

Passing to the limit, for x = a, we have

$$g(x) \equiv G$$
, for $0 < |x-a| < \delta$.

Hence

$$\lim g(x) = +\infty = \eta.$$

Similarly,

$$\lim h(x) = +\infty = \eta.$$

These two equations give 4).

Uniform Convergence

325. 1. A notion of utmost importance in modern mathematics is that of uniform convergence. Let $f(x_1 \cdots x_m; t_1 \cdots t_n)$ be a function of two sets of variables, $x_1 \cdots x_m$ and $t_1 \cdots t_n$.

Let f be defined when $x = (x_1 x_m)$ runs over a domain D and $t = (t, t_*)$ runs over Δ

For each z in D let

$$\lim_{n \to \infty} f(x_1 - x_n, t_1 - t_n) \approx g(x_1 - x_n)$$

Then for each $\epsilon > 0$ and each x in D there exists a $\delta' > 0$, such that

$$|f-g| < \epsilon$$
 (1

for any fin I' . (T)

Evidently if 1) holds for &, it holds for any &', such that 0<8 <8 Of all the values & for which 1) holds at x, let & be the maximum. Then for a given e 8 is a well-defined function of x In D. let $V_{\rm in} \delta \approx \delta_{\rm o}$

Then $\delta_n \leq 0$ If however small ϵ is taken the corresponding δ_n 19 >0 ne bay f converges uniformly to g in D, or is uniformly

convergent Hence if f is uniformly convergent in D, there exists for each €>0 a 8>0 such that

$$f(x_1 \quad x_m \quad t_1 \quad t_n) - g(x_1 \quad x_n) | < \epsilon$$

for any t in I, *(τ) Moreover one and the same norm δ suffices

for all the points of D e being the same The central idea of this case of uniform convergence may be clearly if somewhat roughly brought out by saying that if the convergence is uniform the norms & for which 1) hold, e being small at pleasure but then fixed, do not sink below some definite positive number when a ranges over D

2 These considerations may be extended to the case that 7 is infinite we therefore define as follows

The function $f(x_t x_n t_1 t_n)$ converges uniformly to $g(x_t - x_m)$ in D as $t = \tau$ infinite when for each $\epsilon > 0$, there exists a set of norms p, p, such that for any s in D,

$$f(x_1 - x_m - t_1 - t_n) + g(x_1 - x_m) \Big\} < \epsilon$$
 in $V_{n-1}(\tau)$

In this case of uniform convergence we may say the norms p corresponding to infinite coordinates of \u03c4 cannot become infinitely great, and the norms corresponding to finite coördinates of τ cannot become indefinitely small as x ranges over D, for any given value of ϵ .

3. When $f(x_1 \cdots x_m; t_1 \cdots t_n)$ converges uniformly in D to $g(x_1 \cdots x_m)$, we denote this fact by

$$\lim f(x_1 \cdots x_m; t_1 \cdots t_n) = g(x_1 \cdots x_m), \text{ uniformly.}$$

4. If $f \doteq 0$ uniformly in D, we may say it is uniformly evanescent in D.

326. Ex. 1.

$$f(x, t) = \frac{1}{x + t}$$

$$D = (0*, 1).$$
 $\Delta = (-h, h).$ $h > 0.$

Evidently for any x in D

$$\lim_{t \to 0} f(x, t) = \frac{1}{x} = g(x).$$

But f(x, t) does not converge uniformly to g(x) in D. For if it did, for each t > 0 there must exist a $\delta > 0$, such that

$$R = |f(x, t) - g(x)| = \frac{|t|}{x|x+t|} < \epsilon$$
 (1)

for any t in $V_{\delta}^*(0)$ and any x in D.

Now obviously, t being fixed, R can be made as large as we choose by taking x near enough 0. Hence R does not satisfy 1) as x ranges over D.

In fact, as is seen at once, in order to have $R < \epsilon$, it is necessary to take δ smaller and smaller as x approaches 0. In this case then

 $\operatorname{Min} \delta = 0, \quad \text{in } D.$

327. Ex. 2.

$$f(x, t) = \frac{1}{x+t}$$

$$D = (a, b), 0 < a < b.$$
 $\Delta = (-h, h), h > 0.$

This example is the same as Ex. 1, except D is different.

As before

$$\lim_{t=0} f(x, t) = \frac{1}{x} = g(x).$$

But now f(x, t) converges uniformly to g(x) in D.

In fact, in $V_{\delta}^*(0)$

$$R \leq \frac{\delta}{a(a-\delta)}, \quad \delta < a,$$

wherever x is in D. But we can take δ , such that

$$\frac{\delta}{a(a-\delta)} < \epsilon.$$

Then

$$R < \epsilon$$

for any t in $V_{\delta}^*(0)$ and any x in D; i.e. f converges uniformly in D.

328 Ex. 3
$$f(z, t) = 1 + z^{2} - \frac{1}{(1 + z^{2})^{2}}$$

Here
$$D = (-a \ a) \qquad \Delta = (\alpha, +\infty)$$

$$\lim_{n \to \infty} f(x \ t) = 1 + x^2 \qquad x \neq 0$$

Hence if we set
$$g(x)=0$$
 for $x=0$

$$g(x) = 0$$
 for $x = 0$
= $1 + x^{0}$, for $x \neq 0$,

the have
$$\lim_{z \to \infty} f(z, t) \approx g(z)$$

However, f does not converge uniformly to g in D For, when $x \neq 0$,

$$R = |f(x | t) \sim g(x)| = \frac{1}{(1 + x^2)^2}$$

This shows that as 2 approaches 0 it is necessary to take t larger and larger in order that R < e

There is thus no norm , such that

for each
$$i > \rho$$
 and any x as D
In this case then

Maxe = oo.

Remarks on Dirichlet's Definition of a Function

329 The definition of a function given in 189 and 230 does not depend at all upon an unalytic expression for the function

At first, the reader who has been used only to functions defined by analytic expressions, may be inclined to regard functions not thus defined as only pseudo functions, or at least of little importance

This attitude of mind must be overcome. In the first place, in certain parts of mathematical physics, e g the potential theory, it is of great importance to be able to assign values to a function at pleasure, totally disregarding the question of an analytic expression for it

Secondly, as the reader advances, he will find that many functions which he might well believe have no analytic expression, do indeed have very simple ones

We give now a few examples of such functions

330. 1. For x > 0 let y = 1.

For
$$x = 0$$
 let $y = 0$.

For
$$x < 0$$
 let $y = -1$.

The graph of this function is given - + a in the figure.

An analytic expression of y is

$$y = \frac{2}{\pi} \lim_{n \to \infty} \arctan(nx)$$
.

This function is much used in the Theory of Numbers. We shall call it signum x and denote it by

$$y = \operatorname{sgn} x$$
.

When $u, v \neq 0$ an equation

$$\operatorname{sgn} u = \operatorname{sgn} v$$

simply means that the sign of u is the same as that of v; while

$$\operatorname{sgn} u = +1$$

is only another way of saying that u is positive etc.

331. For $x \neq 0$ let y = 1.

For
$$x=0$$
 let $y=0$.

Its graph is indicated in the $-\infty \leftarrow 0$ figure.

An analytic expression of y is

$$y = \lim_{n \to \infty} \frac{nx}{1 + nx}.$$

332. For $x = 0, \pm 1, \pm 2, \dots$ let y = 0.

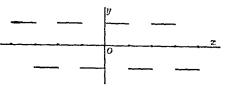

For n < x < n+1, $y = (-1)^n$. n positive integer or 0.

For
$$-(n+1) < x < -n$$
, $y = -(-1)^n$.

The graph of y is indicated in the figure.

An analytic expression of y is

$$y = \lim_{n \to \infty} \frac{(1 + \sin \pi x)^n - 1}{(1 + \sin \pi x)^n + 1}.$$

333 Let f(x), g(x) be two different functions, defined or; w = (0, +∞) The inexperienced reader might well believe that we cannot form an analytic expression which represents f(x) w one pirt of M and g(x) for another part Such an expression w however, the following

$$y = \lim_{x \to 0} \frac{x^x f(x) + g(x)}{x^x + 1}$$

In fact

for
$$x > 1$$
, $y = f(x)$,

for
$$0 \le x \le 1$$
, $y = g(x)$,

for
$$x = 1$$
, $y = \frac{1}{2} \left\{ f(1) + g(1) \right\}$

Ezample Thea

$$f(x)=x^2 \quad g(x)=\cos 2\pi x.$$

334 1 For rational x, let y=a, for irrational x, let y=b, where a b are constants. This function was introduced by Dirichlet.

In any little interval, y jumps infinitely often from a to b and back. It seems highly improbable that such a function should admit a simple analytic expression, yet it does

We have already seen that som x admits a simple analytic

expression Consider now

$$y = a + (b - a) \lim \operatorname{sgn}(\sin^2 n! \pi x) \tag{1}$$

For any rational x, n'x finally becomes and remains an integer. Hence $\sin n' \pi x = 0$ for sufficiently large n

Hence y = a for any rational x

For an irrational x, n'x never becomes an integer. Hence $\sin^2 n' \pi x$ has between 0 and 1, excluding and values

Therefore

$$sgn(sin^2ni\pi x)=1$$
,

and for any irrational x. w= b

Thus 1) is an analytic expression of Dirichlet's function.

The reader should note that it is utterly impossible to intuitionally realize the graph of this function.

2. Similarly, we see that

$$y = f(x) + (g(x) - f(x)) \lim_{n \to \infty} \operatorname{sgn}(\sin^2 n! \pi x)$$

equals

f(x) when x is rational,

and equals

g(x) when x is irrational.

335. A remarkable function is the following. We shall call it Cauchy's function, and denote it by C(x), viz.:

$$C(x) = e^{-\frac{1}{x^2}}, \text{ for } x \neq 0,$$

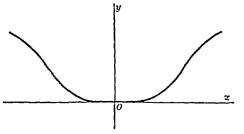

= 0, for $x = 0$.

As a limit, we can write it

 $C(x) = \lim_{u=0} e^{-\frac{1}{x^2 + u^3}}$ $C(x) = \lim_{u=0} e^{-\frac{1}{x^2 + \frac{1}{n}}},$

or

Its graph is given in the figure. Its peculiarity is its remarkable flatness near the origin.

Upper and Lower Limits

336. 1. Let $f(x_1 \cdots x_m) = f(x)$ be defined over D.

Let a be a limiting point of D; a and D may be finite or infinite. Let $A = a_1, a_2, \cdots$ be a sequence of points in D whose limit is a_1 such, however, that

$$L = \lim_{n = \infty} f(a_n)$$

exists, finite or infinite. There are an infinity of such sequences.

For all such sequences, let

$$\lambda = \operatorname{Vin} L, \quad \mu = \operatorname{Viax} L$$

These are called respectively the lower and upper limits of $f(x, x_n)$ at a, we write

$$\lambda = \lim_{n \to \infty} \inf f(x_1 \quad x_n) = \lim_{n \to \infty} f = \lim_{n \to \infty} f$$

The lower and upper limits λ , μ may be infinite

2 When dealing w b functions of a single variable, we can have right and left hand upper and lower limits by considering only values of z>a, or <a, respectively

Then

$$R \lim_{x \to a} \sup f(x) = \lim_{x \to a} \sup f(x) = \overline{\lim}_{x \to a} f(x)$$
$$= R \overline{\lim}_{x \to a} f(x) = \overline{f(x+0)}$$

all denote the right band upper limit of f(x) at a. A similar notation is employed for the left hand limits.

237 Examples.

L
$$y = un^{\frac{1}{2}}$$

 $\lim_{x \to 0} y = -1$ $\lim_{x \to 0} y = +1$.
2 $y = (1 - x^2)uu^{\frac{1}{2}}$
 $\lim_{x \to 0} y = -1$, $\lim_{x \to 0} y = +1$.
3. $y = (1 + x^2)uu^{\frac{1}{2}}$
 $\lim_{x \to 0} y = -1$ $\lim_{x \to 0} x = -1$
4. $y = \lim_{x \to 0} (1 + un^{\frac{1}{2}} + 0 + un^{\frac{1}{2}} - 1)$
See SSS

The reader will do well to roughly akesch the graph of these functions.

We find:

$$y = a + \sin \frac{1}{x-1}, \quad \text{for } x > 1.$$

$$y = b + \sin \frac{1}{x - 1}$$
, for $0 < x < 1$.

Hence

$$R \overline{\lim}_{z=1} y = a+1; \qquad L \overline{\lim}_{z=1} y = b+1;$$

$$R \underline{\lim}_{z=1} y = a-1; \qquad L \underline{\lim}_{z=1} y = b-1.$$

$$\lim_{x \to 1} y = 0 - 1, \qquad \lim_{x \to 1} y = 0 - 1$$

338. 1. Let λ , μ be the lower and upper limits of $f(x_1 \cdots x_m)$ at x = a. Then there exists for each $\epsilon > 0$ a $\delta > 0$, such that

$$\lambda - \epsilon < f(x_1 \cdots x_m) < \mu + \epsilon, \quad \text{in } V_{\delta}^*(\alpha),$$

a, finite or infinite.

For, in the contrary case there exist sequences $A = a_1, a_2, \cdots$ such that

 $\lim f(a_n) < \lambda,$

or

$$\lim f(a_n) > \mu.$$

2. Obviously we have the following:

Let λ , μ be the lower and upper limits of $f(x_1 \cdots x_m)$ at a. There exist two sequences $A = a_1, a_2, \cdots, B = b_1, b_2, \cdots$ whose limits are a, such that $\lim_{n \to \infty} f(a_n) = \lambda, \lim_{n \to \infty} f(b_n) = \mu.$

3. Since the maximum and minimum of a variable exist, finite

or infinite, we have:

The upper and lower limits of a function always exist finite or infinite. If

$$\lim_{r\to 0} f = \lim_{r\to 0} f = L$$

then

$$\lim_{t\to\infty}f=l.$$

CHAPTER VII

CONTINUITY AND DISCONTINUITY OF FUNCTIONS

Definitions and Elementary Theorems

339 1 Let $f(x_1 x_n)$ be defined over a domain D Let $a = (a_1 a_n)$ be a proper limiting point of D. If

$$\lim_{m \to \infty} f(x_1 - x_m) = f(a_1 - a_m),$$

(1

the function f is continuous at a In words of the limit of f at a sa the same as the value of f at a, it is continuous at a

The render should observe that a is not only a limiting point of D but that it lies in D

2 The condition 1) may be expressed in the ϵ δ notation giving the following definition of continuity $f(z_1, x_n)$ is continuous at a if for each $\epsilon > 0$ there exists a $\delta > 0$ such that

$$|f(x_1-x_m)-f(a_1-a_m)|<\epsilon \qquad \text{in } V_4(a)$$

3 A function which is continuous at all the proper limiting points of D is said to be continuous in D. We suppose that D has at least one proper limiting point.

4 Consider the function

We saw, 319, that

$$f(x y) = \frac{xy}{x^2 + y^2}$$
 at points different from the origin

=0, at the origin

$$\lim f(x \ y)$$

does not exist Thus f is not continuous at the origin

At the same time f considered as a function of x alone, or considered as a function of y alone, is continuous.

This example illustrates, therefore, the fact that because $f(x_1 \cdots x_m)$ is a continuous function of each variable separately, we cannot, therefore, assert that f considered as a function of $x_1 \cdots x_m$ is continuous.

340. The following theorems will be found useful in determining whether $f(x_1 \cdots x_m)$ is continuous at α or not.

From 277, 1 and 317, 1 we have at once:

Let $f(x_1 \cdots x_m)$, $g(x_1 \cdots x_m)$ be continuous at a. Then

$$f \pm g$$
, $f \cdot g$,
 $\frac{f}{a}$, $g(a_1 \cdots a_m) \neq 0$

are continuous at a.

341. From 292 and 317, 2 we have at once:

Let
$$u_1 = \phi_1(x_1 \cdots x_n) \quad \cdots \quad u_m = \phi_m(x_1 \cdots x_m)$$

be continuous at $x = a = (a_1 \cdots a_n)$. At x = a, let

$$u_1 = b_1 \quad \cdots \quad u_m = b_m.$$
$$y = f(u_1 \cdots u_m)$$

Let

be continuous at $u = b = (b_1 \cdots b_m)$. Then y considered as a function of the x's is continuous at x = a.

In a less explicit form, we may state this theorem:

A continuous function of a continuous function is a continuous function.

342. In order that $f(x_1 \cdots x_m)$ be continuous at a, it is necessary and sufficient that for each $\epsilon > 0$ exists an undeleted vicinity V(a), such that for any two points x', x'' in it,

$$|f(x')-f(x'')|<\epsilon.$$

This follows at once from 284 and 317, 1.

Continuity of the Elementary Functions

343 The integral rational functions are everywhere continuous Let

$$y = x^a$$
 n positive integer.

Then, by 299, y is continuous at every point z in R Hence, by 340.

$$a_0x^n + a_1x^{n-1} + a_{n-1}x + a_n$$

is everywhere continuous. Thus the theorem is proved for one sariable

Let
$$y = \sum_{i=1}^{n} x_i \cdot x_i$$
,

where the a's are positive integers or 0

$$t = Ax \wedge x \wedge x$$
 (

is continuous at an arbitrary point x For.

Each term of v. viz

let
$$u_1 = r_1^t$$
, $u_n = r_n^t$

Then the term & becomes the product

which, considered as a function of the u's, is continuous, by 340 On the other hand, each u, is a continuous function of the z's Hence, by 341, t, consulered as a function of the 2's, is continuous at every point x in In Hence y, being a sum of the terms t, is centingous, by 340

344 The rational functions are continuous everywhere in their domain of definition D

We saw, in 228, that the domain D of

$$y = \frac{\sum Ax_1^{r_1}}{\sum Bx_1^{r_2}} \frac{x_n^{r_2}}{x_n^{r_2}} = \frac{F}{G}$$

embraces all points of R., except the zeros of the denominator, which are the poles of w

By 343. F and G are everywhere continuous; hence, by 340, p is everywhere continuous, except at the poles of w

345. 1. The circular functions are continuous at every point of their domain of definition.

From 202, we saw that $\sin x$, $\cos x$, are defined for all points of \Re ; while

$$\tan x = \frac{\sin x}{\cos x}, \qquad \cot x = \frac{\cos x}{\sin x},$$

$$\sec x = \frac{1}{\cos x}, \qquad \csc x = \frac{1}{\sin x},$$

are defined for all points of N, except for the zeros of the denominators in the above equations.

From 296, $\sin x$ and $\cos x$ are everywhere continuous. The rest of the theorem follows now from 340.

2. The one-valued functions

are $\sin x$, arc $\cos x$, arc $\operatorname{tg} x$, are $\operatorname{ctg} x$

are continuous at every point of their domains of definition.

This follows at once from 294.

346. 1. The exponential functions are everywhere continuous.

This follows at once from 298, 5.

2. The logarithmic functions are everywhere continuous in their domain of definition.

Let

Then

$$y = \log_b x.$$

$$y = \frac{\log_{e} x}{\log_{e} b}.$$

Hence y is continuous at a point x, if $\log_{x} x$ is. But this is continuous for every x > 0, by 300.

The demonstration also may be given by 294.

Discontinuity

347. If

$$\lim_{m} f(x_1 \cdots x_m)$$

does not exist; or if it exists, and is different from f(a), should f be defined at a, we say f is discontinuous at a, and a is a point of discontinuity of f.

212 CONTINUITY AND DISCONTINUITY OF FUNCTIONS

Discontinuities are of two kinds

Finite discontinuities when f is limited in V*(a)

Infinite discontinuities, when f is unlimited in every Vo(a)

348 We consider now in detail some of the ways in which a function of a single variable f(x) may be discontinuous at a point a

Finite Discontinuities

f(a+0) = f(a-0) + f(a)٦

Such a discontinuity is called a removable discontinuity

Such a function is considered in 331

y = lm - ""

2 f(a+0), f(a-0) exist, but are different Such a function is

y = AED #. considered in 330

3 If f(x) is defined at a, and f(a) = f(a+0), we say f is continuous on the right at a

If f(a) = f(a - 0), f is continuous on the left, at a

4 Either f(a+0) or f(a-0) or both do not exist Such a function is

v - sin 1

We considered this function in 256. Here neither f(0+0) nor f(0=0) exist. Also f is not defined for a - 0

Infinite Discontinuities

349 1 As x approaches a from either side f(x) either mono tone increases or mono tone decreases

Ec. 1 at 0 Er 2

at 0

2. As x approaches a, f(x) increases monotone on one side, and decreases monotone on the other.

ıı v.

Ex. 4.
$$y = \tan x$$
,

at $\frac{\pi}{2}$.

3. As x approaches a, y oscillates infinitely often about a base curve, belonging to the types defined in 1 or 2. The amplitude of the oscillations is limited.

Ex. 5.
$$y = \frac{1}{x^2} + x \sin \frac{1}{x}$$
, at $x = 0$.

Here y oscillates about the base curve

$$y=\frac{1}{x^2};$$

and the amplitude of the oscillations converges to 0 as x approaches 0.

Ex. 6.
$$y = \frac{1}{x} + \sin \frac{1}{x}$$

at x=0.

Here y oscillates about

$$y = \frac{1}{x}; (1$$

and the amplitude of the oscillations remains the same, viz. ±1 above the curve 1).

4. The discontinuities considered in the preceding three cases are such that either $\lim_{x \to a} y$

is infinite, or at least the right and left hand limits at a are infinite and of opposite signs. Such points of discontinuities of f(x) are called *infinities*; we also say f(x) is infinite at such points.

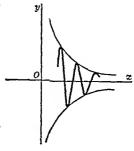

5. In either or both the right and left hand vicinities of a, y is unlimited, while the corresponding (infinite) limits do not exist.

Ex. 7.
$$y = \frac{1}{x} \sin \frac{1}{x} \qquad x = 0.$$

Here y oscillates between the two hyperbolas

$$y=\pm \frac{1}{x}$$

The amplitude of the oscillations increases indefinitely as x approaches 0.

Ex. 8.
$$y = \frac{1}{x} + \frac{1}{x} * n \frac{1}{x} \qquad x = 0.$$
 Here y oscillates about the base curve

y = 1

The amplitude of the oscillations increases indefinitely as x approaches 0.

y - e sin 1 Er. 10. Limy 0 Rimy does not exist. Hern

Some Properties of Continuous Functions

350 1 If f(z, z,) is continuous in a limited perfect domain D it is limited in D

For if f were not hunted

$$\text{Max } f = +\infty$$

Then by 969 there is a point a of D in whose vicinity 1) holds This is impossible for since f is continuous.

$$f(a_1 \quad a_n) - \epsilon < f(x_1 \quad x_n) < f(a_1 \quad a_n) + \epsilon$$
in $V(a)$

2 The theorem 1 does not need to be true if D is not limited

FEANILE $D = (\theta + x) f(x) = x^2$

Here f is continuous a D but f s not him ted.

3 The theorem 1 does not need to hold if D is not perfect

D (0° 1) f(x) 1 EXAMPLE Here f is continuous in D but f is not limited

351 1 At z = a let f(x. z_) be continuous and ±0 Then in F(a) $\operatorname{sgn} f(s_1, z_n) = \operatorname{sgn} f(a_1, a_n)$

For, since f is continuous at a, we have

$$\epsilon > 0, \ \delta > 0, \ |f(x) - f(a)| < \epsilon, \quad V_{\delta}(a).$$

Hence

$$f(a) - \epsilon < f(x) < f(a) + \epsilon$$
.

Since ϵ is arbitrarily small, we can take it so small that

$$f(a)$$
, $f(a) - \epsilon$, $f(a) + \epsilon$

all have the same sign.

2. The thcorcm 1 gives us:

At x = a let $f(x_1 \cdots x_m)$ be continuous and $\neq 0$. Then there exists $a \rho > 0$, such that $|f| > \rho$, in $V(\alpha)$.

352. Let $f(x_1 \cdots x_m)$ be defined over a domain D. By definition, it is continuous in D when, for each proper limiting point x in D,

 $\lim_{h\to 0} f(x_1 + h_1 \cdots x_m + h_m) = f(x_1 \cdots x_m),$

the points x + h lying in D.

If $f(x_1 + h_1 \cdots x_m + h_m)$ not only converges to $f(x_1 \cdots x_m)$ in D, but converges uniformly, we say f is uniformly continuous in D.

We have now the very important theorem:

If $f(x_1 \cdots x_m)$ is continuous in a limited perfect domain D, it is uniformly continuous in D.

Making use of the notation of 325, we have only to show that

$$\delta_0 = \operatorname{Min} \delta$$
, for D

is > 0.

Suppose it were not, i.e. let $\delta_0 = 0$. We show that this assumption leads to a contradiction.

For, by 269, there is a point a in D, such that in V(a)

$$\min \delta = \delta_0 = 0. \tag{1}$$

This is impossible. In fact, by 342, there exists for each $\epsilon > 0$, a δ' , such that for any pair of points x', x'' in $V_{\delta}(a)$

$$|f(x') - f(x'')| < \epsilon. \tag{2}$$

216 CONTINUITY AND DISCONTINUITY OF FUNCTIONS

Let $\delta'' < \frac{1}{2}\delta'$ Let now x' be any point

m I'₁ (a)

Then every point x'' in $V_4(x')$ falls in $V_4(a)$, by 249

Thus, for any such pair of points z', z",

holds
 Thus, for no point x' in V_F(a) does δ sink below δ', and this contradicts 1)

353 Let $f(x_1 x_m)$ be continuous in the limited perfect domain D For each $\epsilon > 0$ there exists a cubical division of D, of norm $\delta > 0$, such that

$$|f(z') - f(z'')| < \epsilon \tag{1}$$

for any pair of points x' x'' in any one of the cells Δ into which D falls

For, since f is uniformly continuous in D, let $\sigma > 0$ be such that

1) holds for any point s^{ij} of $V_{\sigma}(s^{i})$ Let now the norm of the cubical division be $\delta < \frac{\sigma}{\sqrt{s}}$

Suppose z', z'' were a pair of points in some cell Δ , such that 1) does not hold Since

Dist
$$(x', x'') \le \delta \sqrt{m} < \sigma$$
, by 244, 8, 9,

 x^{tt} lies in $V_{\sigma}(x^t)$ But then 1) holds for x^t , x^{tt} . We are thus led to a contradiction

354 1 Let $f(x_1 x_m)$ be continuous in the perfect limited domain D. Then f takes on its extreme values in D.

Before giving the demonstration, let us illustrate the content of this theorem

Let $D = (0^{\circ}, 1^{\circ})$ and $y = x^{\circ}$

Then, for D Max v = +1 Min v = 0

But y does not take on eather of these extremes in D. This is due to the fact that D is not perfect.

2. Let
$$D = (0, +\infty), \text{ and } y = \frac{1}{1+x}.$$

$$\text{Max } y = 1, \text{ Min } y = 0.$$

Thus y takes on its maximum, viz. at x = 0, but does not take on its minimum. This is due to the fact that D is not limited.

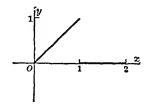

3. Let D = (0, 2),and $y = \lim_{n \to \infty} \frac{x}{x^n + 1}$

This function is a particular case of that in 333.

0 < x < 1, y = x;for $x=1, y=\frac{1}{2};$ for 1 < x < 2, y = 0.

For

Hence $Min \ y = 0, \quad Max = 1.$

The function takes on its minimum value in D, but not its maximum. This is due to the discontinuity of y at 1.

355. 1. We give now the demonstration of 354.

Let e be an extreme of $f(x_1 \cdots x_m)$. Then, by 269, there is a point a in D such that e is an extreme of f in every V(a).

Thus, taking $\epsilon > 0$ small at pleasure, there is at least one point x' in any V(a), such that

$$|f(x') - e| < \frac{\epsilon}{2}. \tag{1}$$

Since f is continuous at a, there is a $\delta > 0$, such that for any x in $V_{\delta}(a)$

$$|f(x) - f(a)| < \frac{\epsilon}{2}. \tag{2}$$

In 2) set x = x', and add to 1); we get

$$|f(a) - e| < \epsilon.$$

$$f(a) = e.$$

Hence, by 87, 5,

2. As corollary we have:

Let $f(x_1 \cdots x_m)$ be continuous and >0 in the perfect limited domain D. Then $\min f > 0$, in D.

356 In the interval $X = (a \ b)$ let f(x) be continuous Let it have opposite says at a and b Then f vanishes for some point e enethen of

Let us form a partition (A B) with the points of M The class A is formed thus Not only shill

$$\operatorname{sgn} f(x) = \operatorname{sgn} f(a)$$
 (1)

at every point of A but between a und any point of A shall 1) hold In B we throw the other points of M

Let c generate it is partition. Then in any V(c) f has opposite signs. But if f(c) were #0 by 251 we could take 8 so small that f(x) has only one sign in I. This leads to a contradiction Hence f(a) = 0

The no at a cannot be an end point of M for at these points $f \neq 0$ by hypothesis

357 Let f(x) be continuous in 9=(a b) Let Min f(x)=a Max f(x) = B in H Then f(x) takes on every value in (a, B) at least once while x passes from a to b

By 354 f(x) takes on its extreme values in M Let, therefore.

$$f(x') = \alpha \quad f(x'') = \beta$$

To fix the ideas, let 0 < a < \$

Let a < y < B Set $g(x) = f(x) - \gamma$

Then

g(x') < 0

 $g(x^{\prime 1}) > 0$

Hence by 356 g vanishes at some point m(x', x'') At this point $f(x) = \gamma$

358 Let y = f(x) be a continuous univariant function in the inter val (a b) Let a = f(a) $\beta = f(b)$ Then the inverse function x = g(y) is a one valued univariant continuous function in (α, β)

By 214 g(y) is a one valued univariant function in its domain of definition E By 357 $E = (\alpha, \beta)$ By 294, g(y) is continuous 10 (a. 8)

The Branches of Many-valued Functions

359. Let $F(x_1 \cdots x_m)$ be a many-valued function in D. We can form a one-valued function $f(x_1 \cdots x_m)$ over a domain $\Delta \leq D$ by assigning to f at each point of Δ one of the values of F at this point, according to some law.

A common way to do this is to assign to f such values that it is continuous in Δ . In this case we say $f(x_1 \cdots x_m)$ is a branch of the many-valued function F.

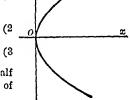

A point, at which two or more branches meet, may be called a branch point.

$$y^2 = x \tag{}$$

defines a two-valued function of x in the interval $(0, +\infty)$. One branch is the one-valued function

 \sqrt{x} ;

the other branch is

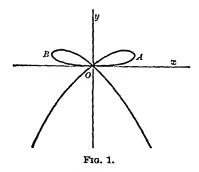

The graph of 2) embraces the points in the upper half of the parabola 1); the graph of 3) is the lower half of this parabola.

361. Ex. 2. The equation

$$x^4 - ax^2y + by^3 = 0$$

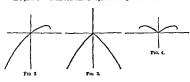

defines a three-valued function of x whose graph is given in Fig. 1.

Still preserving the continuity, we can define the branches of y in several ways, according to the path we take on leaving O.

In any case however we must stop at the posses A B at which the ordinate is tangent to the curve. For if we passed beyond these points, we would no longer have a one-sailed function.

In Figs. 2 3 4 we filmstrate various ways of choosing a branch.

Notion of a Curve

382 1 In elementary mathematics one meets with a great variety of curves. Their equations may be expressed, confining ourselves for the moment to the plane, in one of the three forms

$$y = f(x) \tag{1}$$

$$x = \phi(u), y = \psi(u),$$
 (2)

$$F(xy) = 0 (3)$$

When the curve is given by 1) or 2) it is said to be defined explicitly, when given by 3), it is said to be defined implicitly. We observe that 1) is a special case of 2). For we have only

to write

to reduce 1) to 2) $x = u \quad y = \psi(u),$

When the curve is given by 2), it is said to be expressed in para metric form

We note that 1) is also a special case of 3) For we have only to set

$$F(xy) = y - f(x),$$

to bring 1) to the form 3)

2. It is customarily thought that the notion of a curve is a very simple one; but we shall see that this is not so. On the contrary, it is a very obscure and complex notion. Reserving the discussion of the notion of a curve in general until later, it is well to give a preliminary definition.

Let $\phi(u)$, $\psi(u)$ be continuous one-valued functions of u for an interval $\mathfrak{A} = (a, b)$, finite or infinite.

Set

$$x = \phi(u), y = \psi(u).$$

Let u range over \mathfrak{A} . The points P whose coördinates are x, y will form a point aggregate which we call a curve. The point x, y is the image of the point u.

- Ex. 1. Let $\phi(u) = u$, $\psi(u) = u^2$. The curve so defined is a parabola whose axis is the y-axis.
 - Ex. 2. Let $\phi(u) = a \cos u$, $\psi(u) = b \sin u$. The curve so defined is an ellipse.

Still more generally an aggregate of a finite number of curves may be called a curve C.

Each one of the individual curves which enter in C may be called an arc or part of C.

If a curve or a piece of a curve is such that y is a one-valued monotone function of x, we shall say the curve or the piece of it is monotone. In the same way we shall extend the terms monotone, increasing, univariant, etc., to curves or arcs of curves.

3. Let u range from a to b. If to two different points u', u'' of $\mathfrak{A} = (a, b)$ corresponds the same point P(x, y), this point P will be called a *multiple point* of C.

Let the coördinates xy take on the same pair of values at the end points of $\mathfrak{A}=(a,b)$. Then C is called a closed curve. If C has no multiple points in (a,b^*) , we shall say C is a closed curve without multiple points.

4. The extension of these notions to n-dimensional space, by setting

 $x_1 = \phi_1(u), \cdots x_n = \phi_n(u),$

is too obvious to need comment.

CHAPTER VIII

DIFFERENTIATION

FUNCTIONS OF ONE VARIABLE

Definitions

363 I et y = f(x) be defined over a domain D for which a is a proper limiting point. The quotient

$$\frac{\Delta y}{\Delta x} = \frac{f(x) - f(a)}{x - a}, \quad x \in \mathcal{D}, \quad (1)$$

is called the difference quotient at a If we set x = a + h we have also

$$\frac{\Delta y}{\Delta x} = \frac{f(a+h) - f(a)}{h}.$$
 (2)

Let

$$\lim_{x\to 0} \frac{\Delta y}{\Delta x} = \eta \tag{3}$$

exist finite or infinite. Then η is called the differential coefficient of f(z) at a, and is denoted by

Let Δ be the aggregate of points in D for which η is finite or infinite. The corresponding values of η define a function of z, called the deritative of f(z) more specifically, the first derivative of f(z). It is represented variously by

$$f'(x) D_x f(x) \frac{df}{dx}, \frac{dy}{dx}$$
 (4)

The function f'(x) is said to be obtained from f(x) by the process of differentiation. A function which admits a derivative is said to be differentiable.

Since f'(x) may be infinite, the reader will observe that its values lie in $\overline{\Re}$. Cf. 276.

364. In the same way, the right and left hand limits at x = a,

$$R \lim \frac{\Delta y}{\Delta x}, \quad L \lim \frac{\Delta y}{\Delta x},$$

give rise to right and left hand differential coefficients at a. These we denote by Rf'(a), Lf'(a).

These in turn give rise to right and left hand derivatives, which we may denote, prefixing R and L before the symbols, 4) in 363.

When speaking of differential coefficients and derivatives in the future, we shall mean those defined in 363, unless the contrary is expressly stated.

However, much that we prove for f'(a) and f'(x) may be applied at once to the corresponding unilateral differential coefficients and derivatives.

Geometric Interpretations

365. Let P and R be the points on the graph of

$$y = f(x)$$
,

corresponding to x=a and $x=a+\Delta x$, Fig. 1.

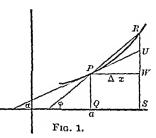

Then

$$PW = \Delta x = h$$
, $RW = \Delta y$.

If the secant PR makes the angle ϕ with the x-axis,

$$\frac{\Delta y}{\Delta x} = \frac{RW}{PW} = \tan \phi.$$

That is: the difference quotient is the tangent of the angle that the secant makes with the x-axis.

Suppose now y is continuous in a little interval about x = a, if the secant PR approaches a limiting position PU, as R approaches the fixed point P from either side, we say PU is the tangent to the curve at P.

Evidently, if f'(a) is finite,

$$f'(a) = \lim_{\Delta x} \frac{\Delta y}{\Delta x} = \lim_{\Delta x} \tan \phi = \tan \alpha$$

where α is the angle that the tangent line makes with the x axis. If $f'(a) = \pm \infty$, the tangent line is parallel to the y axis

Such cases are shown in Figs 2 and 3

The point P is a point of inflection with vertical langent
For an example of such a function, see 338, 5

366 1 When the differential coefficient at a does not exist, finite or infinite the right and left differential coefficients may They are then different

If both are finite we have a case illustrated by Fig. 1

Such a function is

out a function is
$$f(z) = z \stackrel{r-1}{r}, \quad \text{for } z \neq \emptyset,$$

$$c + 1 = 0, \quad \text{for } z = 0$$
 Fro 1

If one is finite and the other infinite, we have a case illustrated by Fig. 2

The points P in Figs 1, 2 are called angular

2. When both differential coefficients are infinite, but of opposite signs, we have a case illustrated by Figs. 3, 4.

Here P is a cusp with vertical tangent. See 388, 3 for an example of such a function.

3. In Case 1 the curve has not one but two tangents at P; viz. a right and a left hand tangent. Case 2 may be considered as a special or limiting case of 1. The curve has a tangent at P.

In both cases the direction of motion along the curve changes abruptly.

When we say "a curve has at every point a tangent," we exclude Case 1.

Non-existence of the Differential Coefficient

367. 1. We consider now some examples of continuous functions for which the differential coefficient ou either side of certain points does not exist.

Let

$$y = f(x) = x \sin \frac{\pi}{x}$$
 for $x \neq 0$;

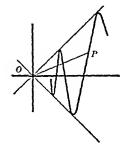

$$=0, \qquad \text{for } x=0.$$

The graph Γ of y is given in the adjoining figure.

Evidently Γ oscillates between the two lines

$$y=\pm x, \qquad (1$$

with increasing rapidity as x approaches 0.

For $x \neq 0$ y is evidently continuous For x = 0 y is also continuous, since

$$\lim_{x \to 0} x \sin \frac{\pi}{x} = 0$$

At the origin the secant line OP oscillates between the two lines I) and obviously does not approach any fixed position as P approaches 0 from eitler side. Thus T has no tangent at all at O This result is verified at once analytically

For

$$\frac{\Delta y}{\Delta x} = \sin \frac{\pi}{\Delta x}, \quad \text{st } x = 0,$$

and as $\Delta z = 0$ sin $\frac{\pi}{\Delta z}$ oscillates infinitely often between ± 1

2 For use later let us find $\frac{dy}{dx}$ for $x = \frac{1}{n}$ We have setting $\Delta x = h$

$$\frac{\Delta y}{\Delta x} = \frac{1}{h} \left(\frac{1}{n} + h \right) \sin \frac{\tau}{1 + h}$$

$$= \frac{1 + nh}{n!} \sin \frac{n\pi}{1 + n!}$$

But

$$\sin \frac{n\pi}{1+nh} = \sin \left(n\pi - \frac{n^2\pi h}{1+nh}\right) = -(-1)^4 \sin \frac{n^2\pi h}{1+nh}$$

Hence, setting

$$u = \frac{n^2 \pi h}{1 + nh},$$

$$\frac{\Delta y}{\Delta z} = -(-1)^n n\pi \frac{\sin n}{z},$$

and thus

$$\lim_{x \to 0} \frac{\Delta y}{\Delta x} = -(-1)^n n\pi \lim_{x \to 0} \frac{\sin u}{u}$$

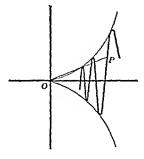

$$= -(-1)^n n\pi, \text{ by } 301$$

368. Let
$$y = f(x) = x^2 \sin \frac{\pi}{x}, x \neq 0;$$

= 0, $x = 0.$

Evidently y is everywhere continuous even at 0.

The graph Γ of y oscillates between the two parabolas $y = \pm x^2$

with increasing rapidity as x approaches 0.

As P approaches 0, the secant OP oscillates between narrower and narrower limits, which limits converge on both sides toward the x-axis. Evidently,

$$f'(0) = \lim \frac{\Delta y}{\Delta x} = 0;$$

and Γ has a tangent at 0, viz. the axis of x.

This result is verified analytically at once.

For,

$$\frac{\Delta y}{\Delta x} = \Delta x \sin \frac{\pi}{\Delta x} \text{ at } 0,$$

and

$$\lim_{\Delta x=0} \Delta x \sin \frac{\pi}{\Delta x} = 0.$$

369. Let $A = 0, \pm 1, \pm \frac{1}{2}, \pm \frac{1}{3}, \cdots$

For x not in A, let
$$y = f(x) = x \sin \frac{\pi}{x} \sin \frac{\pi}{\sin \frac{\pi}{x}}$$
.

For x in A, let y = 0.

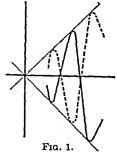

Here y is everywhere continuous, even at the points of A.

Let C be the graph of y, and Γ the graph of

$$y_1 = x \sin \frac{\pi}{x},$$

considered in 367.

In Fig. 1, the full curve represents an arc of Γ for an interval $I_n = (a_n, b_n)$, $a_n = \frac{1}{n}$, $b_n = \frac{1}{n-1}$. The dotted curve, call it Γ' , is symmetrical to Γ .

We observe now that y is obtained by multiplying the ordinate w, of I' by the factor

$$y_3 = \sin \frac{\pi}{\sin \frac{\pi}{\pi}}$$

As x approaches an end point of I.

Hence y2 oscillates infinitely often between ±1 The effect of the factor yo in y = yay, is thus to bend I' in I, an

infinite number of times, so that the resulting curvea portion of C lies between I and I'

This is represented in Fig. 2 where the light and dotted curves are I and I' and the heavy curve is P

At one of the pants of A as a, the secant a.P oscillates with increasing rapidity as P approaches a. from either aide

$$\frac{dy_1}{dz} = -(-1)^n n\pi$$
, by 367, 2,

the tangents to Γ and Γ' are not the x axis Hence the limits of oscillation of the secant do not converge to 0 and hence the secant a.P does not converge to some fixed position as x approaches a.

Thus y has no differential coefficient at any point of A, and its graph C has at these points no tangent

Since 0 is the limiting point of A there are an infinity of these singular points in the vicinity of the origin

370 let
$$A = 0 \pm 1, \pm 2$$
,
For x not in A let $y = f(x) = x^2 \sin \frac{\pi}{x} \sin \frac{\pi}{\sin \frac{\pi}{x}}$
For x in A let $y = 0$

The reasoning of 369 may be applied here The graph of y oscillates between the two curves

discussed in 368

Susce

There is no tangent at the points ± 1 , ± 2 , ... while at the origin there is a tangent, viz. the x-axis.

The graph C of y presents therefore this peculiarity: in the vicinity of the origin there are an infinity of points at which C has no tangents; yet at the origin itself C has a tangent.

371. In 369 and 370, the aggregate A is of the first order, by 263, 2.

It is easy by the process of iteration to form continuous functions which have no differential coefficient over an aggregate A, of order m.

Let
$$\theta(x) = \sin \frac{\pi}{x}$$
 and
$$y = x\theta(x)\theta^{(2)}(x) \cdots \theta^{(m+1)}(x).$$

This expression does not define y at points involving division by zero. At these points, call their aggregate A, we set y=0. It is easy to show that y is everywhere continuous and that it has neither right nor left hand differential coefficients at any point of A. The aggregate is of order m. See 259, 260.

Fundamental Formulæ of Differentiation

372. As many American and English works on the calculus derive these formulæ in an incorrect or incomplete manner, we shall deduce some of them here. We shall, at the same time, prove them under conditions slightly more general than usual. As domain of definition D of our functions y, u, v, \cdots we take any aggregate having proper limiting points. The domain of definition Δ of their derivatives will embrace, at most, the proper limiting points of D.

It is convenient to represent

and

$$y(x+h), \ u(x+h), \cdots \text{ by } \overline{y}, \ \overline{u}, \cdots \text{ etc.},$$

$$\frac{dy}{dx}, \frac{du}{dx}, \cdots \text{ by } y', \ u', \cdots \text{ etc.}$$

373 We begin by proving

If the differential coefficient f'(a) is finite, f(x) is continuous at a

For, since

$$\lim_{k\to 0}\frac{f(a+k)-f(a)}{k}=f'(a),$$

we have, for each $\epsilon > 0$, a $\delta > 0$ such that, if $|k| < \delta$,

$$\frac{f(a+h)-f(a)}{i}=f'(a)+\epsilon' \qquad |\epsilon'|<\epsilon$$

..

Hence
$$f(a+k) = f(a) + h(f'(a) + e')$$
 Therefore,
$$\lim_{n \to \infty} f(a+k) = f(a),$$

which states that f is continuous at a

374 If y is constant in D, y' = 0

For

$$\frac{\Delta y}{\Delta x} = 0,$$
for any point of D

for any point of D

375 Let $y = u \pm v$ Let u', v' be finite in Δ Then $y' = u' \pm v'$ in Δ

For

For

$$\frac{\Delta v}{\Delta v} = \frac{\Delta u}{\Delta u} \pm \frac{\Delta v}{\Delta v} \qquad (1)$$

(1

(2

Since u', v' exist and are finite, we can apply 277, 2, to 1)

378 Let y = uv Let u'. v' be finite in ∆

Then, in Δ , v' = uv' + vv'

 $\frac{\Delta y}{\Delta z} = \frac{uv - uv}{\Delta z} = \frac{(u + \Delta u)(v + \Delta v) - uv}{\Delta z}$

$$\frac{\Delta y}{\Delta x} = \frac{(u + \Delta u)(v + \Delta v) - uv}{\Delta x}$$

$$\frac{u\Delta x}{u\Delta x} + u\Delta u = \frac{(u + \Delta u)(v + \Delta v)}{\Delta x}$$

$$= \frac{u\Delta x + v\Delta u}{\Delta x} = u\frac{\Delta x}{\Delta x} + v\frac{\Delta u}{\Delta x}$$

By 373,

 $\lim \bar{u} = u$.

By hypothesis,

$$\lim_{\Delta u} \frac{\Delta u}{\Delta x} = u', \lim_{\Delta u} \frac{\Delta v}{\Delta x} = v'.$$

Hence, passing to the limit in 2), we get 1).

377. 1. Let $y = \frac{u}{v}$. Let u', v' be finite and $v \neq 0$, in Δ . Then $y' = \frac{vu' - uv'}{c^2}, \text{ in } \Delta. \tag{1}$

For
$$\frac{\Delta y}{\Delta x} = \frac{v\Delta u - u\Delta v}{v\overline{v}\Delta x} = \frac{1}{\overline{v}}\frac{\Delta u}{\Delta x} - \frac{u}{v} \cdot \frac{1}{\overline{v}}\frac{\Delta v}{\Delta x}.$$
 (2)

By 373,

 $\lim \bar{v} = v$.

By hypothesis,

$$\lim \frac{\Delta u}{\Delta x} = u', \lim \frac{\Delta v}{\Delta x} = v'.$$

Passing now to the limit in 2), we get 1).

We observe, by 351, that $\bar{v} \neq 0$ for Δx sufficiently small, since v is continuous and $\neq 0$ at x. It is therefore permissible to divide by \bar{v} , as in 2).

2. Criticism. Some writers derive 1) as follows. From

$$y = \frac{u}{v}$$

they get

$$yv = u$$
.

They now apply 376, which gives

$$u' = yv' + vy', (3)$$

which, solved, gives 1).

This method is incorrect. For to get 3), by using 376, we must impose the condition that y' exists and is finite. But nothing in this form of demonstration shows the existence of y'. The method then shows only this: on the assumption that y' exists, its value is given by 1). But this assumption of existence makes the demonstration worthless.

3 Many writers of elementary mathematical text books are not alive to the fact that a demonstration, which involves an assumption of the existence of certain quantities or forms, renders the demonstration invalid. Thus error of reasoning is extremely common in the calculus. Because determinate results are obtained by such reasoning, it is allowed to pass a conclusive.

To show how fallacious this style of reasoning is, let us assume that we can write .

$$\frac{1}{x^2-1} = a \sin x + b \cos x$$

Granting this, it is easy to determine a and b. In fact, setting x = 0 we get

Setting $x = \frac{\pi}{2}$, we get

$$a = \frac{4}{\pi^3 - 16}$$

Hence

$$\frac{1}{x^2-4} = \frac{4}{\pi^2-16} \sin x - \frac{1}{4} \cos x,$$

a perfectly determinate result but also a perfectly false result. In fact, the right side of 4) is a periodic function, while the left side is not

The reader should therefore not begrudge the pains it is some times necessary to also, to prove an existence theorem. He should also notice that by modifying the form of profit it is sometimes possible to avoid assuming the existence of certain things which enter the demonstration. Writness the demonstrations just given of 1) in 1, 2.

378 Let y = f(x) and x = g(t) Let $g'(t) = \frac{dx}{dt}$ be finite in TLet X be the image of T. If $\frac{dy}{dx} = f'(x)$ is finite in X,

$$\frac{dy}{dt} = \frac{dy}{dt} \cdot \frac{dx}{dt}.$$
(1)

[•] In treating the decomposition of a rational function into partial fractions it is often assumed without any justification that the decomposition in the form desired is poss bla-

Before proving this theorem, we wish to illustrate two cases which may occur.

Ex. 1. Let $x = t \sin 2 m\pi t$. The period of $\sin 2 m\pi t$ considered as a function of $t \sin \frac{1}{m}$. By taking m very large but fixed, x will oscillate a great many times near the origin. Where the graph cuts the t-axis, i.e. when

$$\Delta t = \pm \frac{1}{2m}, \pm \frac{1}{m}, \pm \frac{8}{2m}, \cdots$$

we have $\Delta x = 0$.

But however large m is taken, we can determine a $\delta > 0$, such that $\Delta x \neq 0$, in $V_{\delta} = 0$. In fact, we have only to take $\delta < \frac{1}{2m}$.

What we have shown for t=0 is true for any other point t. That is, we can always choose δ sufficiently small so that in $V_{\delta}^*(t)$, Δx shall not $\succeq 0$.

Ex. 2.
$$x = t^2 \sin \frac{\pi}{t}, \text{ for } t \neq 0;$$
$$= 0, \qquad \text{for } t = 0.$$

The graph of this function we considered in S68. For any point $t \neq 0$ we can determine a δ such that in $V_{\delta}^*(t)$, Δx does not vanish. Not so at t = 0. Here, however small $\delta > 0$ is taken, x oscillates infinitely often in $V_{\delta}^*(0)$; and thus for an infinity of points in $V_{\delta}^*(0)$, $\Delta x = 0$.

We can, however, throw the points of $V_{\delta}^*(0)$ in two sets. In one, call it V_0 , we put the points for which $\Delta x = 0$. Then

$$V_0 = \pm \frac{1}{m}, \pm \frac{1}{m+1}, \cdots$$

In the other set, call it V_1 , we put all the other points of V^* . We can now show for the function y = f(x) in the above theorem, that 1) is true for each one of these sets of points, and therefore true for both together.

379. We give now the proof of 378.

Let t be any point in T; let x be the corresponding point in X. Let Δx , Δy be the increments of x, y, corresponding to the increment Δt of t.

Case 1. There exists a $T^*(t)$, in which $\Delta x \neq 0$.

The identity

$$\frac{\Delta y}{\Delta t} = \frac{\Delta y}{\Delta x} \cdot \frac{\Delta x}{\Delta t} \tag{1}$$

does not involve a division by 0, as $\Delta x \neq 0$.

Since $\frac{dx}{dt} = g'(t)$ is finite at t, $\Delta x = 0$ when $\Delta t = 0$ Hence, if 292,

$$\lim_{\Delta y} \frac{\Delta y}{\Delta z} = \lim_{\Delta y} \frac{\Delta y}{\Delta z} = \frac{dy}{dz}.$$

Thus,

$$\lim_{z \to 0} \frac{\Delta y}{\Delta \varepsilon} = \lim_{z \to 0} \frac{\Delta y}{\Delta x} \cdot \lim_{z \to 0} \frac{\Delta x}{\Delta t},$$

and

$$\frac{dy}{dt} = \frac{dy}{dx} \frac{dx}{dt}, \qquad (1)$$

which proves the theorem for this case

Case 2 $\Delta x = 0$ for some point in every $V^*(t)$.

Let Γ_a be the points of $\Gamma^a(t)$, for which $\Delta z = 0$.

Let V_t be the remaining points of $V^*(t)$

If we show

$$\lim \frac{\Delta y}{\Delta t}$$
, and $\frac{dy}{dx} \lim \frac{\Delta x}{\Delta t}$, (8)

have one and the same value for every sequence of points whose limit is t we have proved 2) for this case

Let A be any sequence in I'. Then

$$\lim_{t \to \infty} \frac{\Delta x}{\Delta t} = 0, \quad (4)$$

since $\Delta x = 0$ for every point in A

As $\frac{dy}{dx}$ is finite at x,

$$\frac{dy}{dx} \lim_{\Delta x} \frac{\Delta x}{\Delta x} = 0$$

On the other hand,

$$\lim_{t\to\infty}\frac{\Delta y}{\Delta t}=0.$$

For, Δx being 0 for every point of A, y = f(x) receives no increment, and hence $\Delta y = 0$ in A

Thus, for every sequence A, the two limits in 3) have the same value, viz 0

Let now B be any sequence in V_1 which $\doteq t$. Let the image of the points B be the points C, on the x-axis.

Then, by 292,

$$\lim_{B} \frac{\Delta y}{\Delta t} = \lim_{C} \frac{\Delta y}{\Delta x} \cdot \lim_{B} \frac{\Delta x}{\Delta t}$$

$$= \frac{dy}{dx} \lim_{B} \frac{\Delta x}{\Delta t}.$$
(5)

Thus the two limits of 3) are the same for each sequence B. It remains to show that one is 0. Now, by 4),

$$\lim_{B} \frac{\Delta x}{\Delta t} = \lim_{A} \frac{\Delta x}{\Delta t} = 0;$$

since, by hypothesis,

$$\lim \frac{\Delta x}{\Delta t} = g'(t)$$

for any sequence whose limit is the point t.

Hence the right side of 5) is 0.

Thus the two limits 3) have the value 0 for every sequence A or B. These limits therefore have the value 0 for any sequence, whether its points all lie in V_0 , or in V_1 , or partly in V_0 and partly in V_1 .

380. The demonstration, as ordinarily given, rests on the identity

 $\frac{\Delta y}{\Delta t} = \frac{\Delta y}{\Delta x} \cdot \frac{\Delta x}{\Delta t}.$

The theorem is, therefore, only established for functions x=g(t), which fall under Case 1.

If one wishes to give a correct but elementary demonstration, it would suffice to restrict y(t) to have only a finite number of oscillations in an interval T, and have at each point of T a finite differential coefficient. In an elementary text-book on the calculus it is not advisable to consider functions with an infinite number of oscillations.

381. Let y = f(x) be univariant and continuous. Let x = g(y) be its inverse function. Let f'(x) be finite or infinite in Δ . Let E be the image of Δ . Let x and y be corresponding points in Δ and E.

If
$$f'(x)$$
 is finite and $\neq 0$, then $g'(y) = \frac{1}{f'(x)}$
If $f'(x) = 0$ then $g'(y) = \begin{cases} +\infty & \text{if } f \text{ is increasing} \\ -\infty & \text{if } f \text{ is decreasing} \end{cases}$
If $f'(x)$ is infinite $g'(y) = 0$

Since f is univariant, Δy and therefore also $\frac{\Delta y}{\lambda_0}$ are $\neq 0$.

Hence the relation

$$\frac{\Delta x}{\Delta y} = \frac{1}{\frac{\Delta y}{\Delta z}}$$
 (1

does not involve for any point a division by 0

Since y is continuous, $\Delta y = 0$ when $\Delta x = 0$

We have therefore only to apply 292 in passing to the limit in 1)

382 The geometric interpretation of 381 is very simple in the following case

Let y = f(x) be a continuous increasing function in $(a \ b)$

The inverse function x = g(y) is increasing and continuous in (α, β) See Fig.

The graph of f(x) and g(y) is the same curve C. At P_1 , P_2 we have points of inflection

If PT is the tangent at P.

$$\tan \phi = f'(x) = \frac{dy}{dx}$$

$$\tan \theta = g'(y) = \frac{dx}{dy}$$

Since

$$\theta + \phi = \frac{\pi}{2},$$

$$\tan\theta = \frac{1}{\tan\phi},$$

or

$$\frac{dx}{dy} = \frac{1}{\frac{dy}{dx}}.$$

The consideration of the tangents at P_1 , P_2 illustrates the theorem for the other cases.

383. We apply the preceding general theorems to find the derivatives of some of the elementary functions, choosing those whose demonstration is often given incorrectly.

$$D_x a^x = a^x \log a. \qquad a > 0, x \text{ arbitrary.}$$
 (1)

For, let

$$y = a^x$$
.

Then

$$\frac{\Delta y}{\Delta x} = a^x \frac{a^{\Delta x} - 1}{\Delta x}.$$

But, by 311,

$$\lim_{\Delta x = 0} \frac{a^{\Delta x} - 1}{\Delta x} = \log a.$$

Passing to the limit in 2), we get 1).

When a = e, 1) becomes

$$D_x e^x = e^x. (3)$$

384. 1.
$$D_x \log x = \frac{1}{x}$$
. $x > 0$. (1)

Let

$$y = \log x$$
.

Then

$$x=e^{y}$$

But

$$\frac{dx}{dy} = e^y = x,$$

From 2) we get, by 381,

$$\frac{dy}{dx} = \frac{1}{x}$$

which is 1).

2 We can get 1) directly as follows

$$\frac{\Delta y}{\Delta z} = \frac{\log(z + \Delta x) - \log z}{\Delta z} = \frac{\log\left(1 + \frac{\Delta z}{z}\right)}{\Delta z}$$

$$= \frac{\log\left(1 + \frac{\Delta z}{z}\right)}{2}$$

$$= \frac{1}{x} \frac{\log\left(1 + \frac{\Delta x}{x}\right)}{\Delta x}$$
 (3)

But, by 310 and 292,

$$\lim_{x \to \infty} \frac{\log\left(1 + \frac{\Delta x}{x}\right)}{\Delta x} = 1. \tag{4}$$

0

Hence passing to the limit in 3) we get 1) again from 1) we can prove again

 $D_{s}e^{s}=e^{s}$ For, from $y=e^{s}$

$$y = e^{t}$$
,
 $x = \log y$

Hence, by 1),

$$\frac{dx}{dy} = \frac{1}{y}$$

Using 881 we have

$$\frac{dy}{dx} = y = e^{x},$$

which is 5)

we have

----/

385 1 Criticism In either of the preceding ways of getting

we need the limit $D_x e^x$ and $D_x \log x$

$$\lim_{n\to 0} (1+u)^n = e \tag{1}$$

Some writers only prove 1) when a runs over the sequence

1 3 1 Others prove 1) only for a right hand limit As however, Δz may have any positive or negative values as it converges to 0, the

limit 1) must be established without any restriction

2. If the method of 384, 2 is used to get $D_x \log x$, we must not only prove 1), but we must show that

$$\lim_{u=0} \log (1+u)^{\frac{1}{u}} = \log \lim_{u=0} (1+u)^{\frac{1}{u}}.$$

This is rarely done.

3. A third method is to employ the Binomial Theorem, which is taken from algebra.

The rigorous demonstration of this theorem for any case, besides that of integral positive exponents, is far beyond the limits of the ordinary high school or college algebra. Moreover, the demonstrations usually given are incorrect. The employment of the Binomial Theorem to find the above derivatives is therefore open to the most serious criticism.

386. 1. The differentiation of the direct circular functions presents nothing of note; let us therefore turn at once to the *inverse* circular functions.

We take
$$y = \arcsin x$$
 (1)

as an example. The notation indicates that we have taken the principal branch of $\arcsin x$, [223]. Then

$$-\frac{\pi}{2} \le y \le \frac{\pi}{2}.\tag{2}$$

From 1) we have

$$x = \sin y$$
.

Hence

$$\frac{dx}{dy} = \cos y = \sqrt{1 - x^2}.$$
 (3)

The radical has the positive sign, as $\cos y$ is not negative for the values 2).

Hence, by 381,

$$\frac{dy}{dx} = D_x \arcsin x = \frac{1}{\sqrt{1 - x^2}}, \quad |x| \neq 1.$$

$$= + \infty \text{ for } x = \pm 1.$$

2. Criticism. In many books the branch of $arc \sin x$ which is taken is not specified. Consequently, the sign of the radical in 3) is not specified. For some branches the negative sign should be taken.

387 1
$$D_x x^+ = \mu x^{x-1}$$
 $x > 0$, μ arbitrary. (1)

(2

Then y = e* logs.

Let $\mu \log x = u$

Then $y = e^{x}$

But $\frac{dy}{dx} = \frac{dy}{dx} \frac{du}{dx}$.

and $\frac{dy}{dt} = e^{x}, \frac{du}{dt} = \frac{\mu}{2}$

Hence $\frac{dy}{dx} = \mu x^{-1}$

2 Criticism Some writers rest the demonstration on

$$\lim \frac{\log(1+u)}{1+u},$$

and are thus open to the criticism of 385, 2 Others proceed thus From 2) we have $\log v = \mu \log x$

Differentiating both sides, we get

$$\frac{1}{y}\frac{dy}{dz} = \frac{\mu}{z}$$

from which we get 1) at ouce This method rests on the assump tion that dy exists, and so is open to the criticism of 377, 2.

EXAMPLES

388 1 $y = a + b\sqrt{x^2} = f(x)$

For x > 0, we can apply 387, getting, since here $\mu = \frac{3}{2}$,

$$\frac{dy}{dz} = \frac{2}{3} \frac{b}{\frac{3}{2}C}$$
(1)

2. For $x \le 0$, the formula of 387 is inapplicable, since it rests on the essential hypothesis that x > 0. We can, however, adopt a method applicable to any $x \ne 0$.

Set $x^2 = u$.

Then

$$y = a + bu^{\frac{1}{3}}.$$

For all x in \Re which are $\neq 0$, u is >0. Applying 387, we have

$$\frac{dy}{du} = \frac{1}{3}bu^{-\frac{1}{3}}$$

On the other hand, by 378,

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx},$$

since

$$\frac{du}{dx} = 2x$$

is finite.

Hence

$$\frac{dy}{dx} = \frac{2}{3} \frac{b}{\sqrt[3]{x}}$$

3. When x = 0, even this method fails, as u must be > 0, in order to apply 387. In order to calculate the differential coefficient at this point, we must start from its definition.

We have, setting $h = \Delta x$,

$$\frac{\Delta y}{\Delta x} = \frac{f(h) - f(0)}{h} = b \frac{\sqrt[3]{h^2}}{h}$$

Here, when $\Delta x \doteq 0$,

$$R \lim \frac{\Delta y}{\Delta x} = +\infty$$
, $L \lim \frac{\Delta y}{\Delta x} = -\infty$. Fig. 1.

The graph of f(x) has thus a vertical cusp at the origin, as in Fig. 1.

4 In order to get

some readers may be tempted to take the right and left hand limits of the expression 1) for x=0. In the present case we would get the correct result. In general, if the expression for f'(x) assumes an indeterminate form for a particular value of x, say x=a, the reader must avoid the temptation to conclude that

$$f'(a) = \lim_{x \to a} f'(x)$$

This is only true when f'(x) is continuous at a.

$$f(z) = x \sin \frac{1}{z} z \neq 0$$

Here f'(0) does not exist by 367 while for $x\neq 0$,

$$f(x) = \sin \frac{1}{x} - \frac{1}{x} \cos \frac{1}{x}$$

Thus also does not swist. $\lim_{x \to 0} f'(x)$ $f(x) = x^{2} \sin \frac{1}{x} x \neq 0,$

llere = 0 2:

f(0) = 0 by 368while for $z \neq 0$,

 $f(x) \approx 2 x \sin \frac{1}{x} - \cos \frac{1}{x}$

does not exist.

lm f (z)

5 Let

Thus

 $f(x) = x^{\frac{1}{2}}$

We find readily that

$$Rf'(0) = Lf'(0) = +\infty$$

The graph is given in Fig 2

389. 1. Let
$$\log x = l_1 x$$
, $\log \log x = l_2 x$,

$$\log \log \log x = l_3 x$$
, etc.

Since $\log u$ is defined only for u > 0, we shall suppose that x is taken sufficiently large so that $l_m x$ has a meaning.

We prove now

$$D_x l_m x = \frac{1}{x} \cdot \frac{1}{l_1 \times l_2 \times \cdots l_{m-1} x}, \qquad m > 1.$$
 (1)

For, first, let

$$y = l_0 x = \log \log x$$
.

Set

$$u = \log x$$
.

Then

$$y = \log u$$
.

Hence

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx} = \frac{1}{u} \cdot \frac{1}{x} = \frac{1}{x} \frac{1}{\log x} = D_x l_2 x. \tag{2}$$

Next, let

$$y = l_3 x = \log \cdot l_2 x.$$

Set

$$u=l_2x$$

Then

$$y = \log u$$
.

Hence

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx}$$

By 2),

$$\frac{du}{dx} = D_x l_2 x = \frac{1}{x} \frac{1}{\log x}.$$

Hence

$$\frac{dy}{dx} = \frac{1}{u} \cdot \frac{1}{x \log x} = \frac{1}{x l_0 x l_0 x} = D_x l_0 x.$$

By induction, we now establish 1) readily.

2. In a similar manner we establish

$$D_x l_x^{1-\lambda} x = \frac{1-\lambda}{x l_1 x l_2 x \cdots l_{s-1} x l_s^{\lambda} x}, \qquad \lambda \neq 1.$$
 (3)

From 1), 3) we have two formulæ to be used later

$$D_{x} = \frac{1}{x-a} = \frac{-1}{(x-a)l_{x} - \frac{1}{2} - \frac{1}{2}}, \quad m > 1.$$
 (4)

and

$$D_{x}l_{m}^{1-\lambda}\frac{1}{x-a} = \frac{\lambda-1}{(x-a)l_{1} - l_{n-1} - l_{n-1} - l_{n-1}} \qquad \lambda \neq 1 \quad (5)$$

In 4), 5) we suppose x>a, such that the quantities entering them are defined

Differentials and Infinitesimals

390 1 Since

$$f'(x) = \lim \frac{\Delta y}{\Delta x},$$

we have for each $\epsilon > 0$, a $\delta > 0$, such that in $V_i^{\bullet}(x)$,

 $\left|\frac{\Delta y}{\Delta x} - f'(x)\right| < \epsilon,$

or $|\Delta y - f'(x)\Delta x| < \epsilon |\Delta x|_0$

 $|\Delta y - f'(x)\Delta x| < \epsilon |\Delta x|,$

or $\Delta v = f'(z)\Delta z + c'\Delta z$.

where

(1

V e call

 $f'(x)\Delta x$

the differential of
$$f(x)$$
, and denote it by dy or $df(x)$

The relation 1) shows that Δy is made up of two parts, viz

The ratio of these two parts is

$$\frac{\epsilon'}{f'(x)} \qquad f'(x) \neq 0$$

As f'(x) is fixed, for fixed x, and ϵ' can be made numerically as small as we please, by taking δ sufficiently small, we see that the part $\epsilon' \Delta x$ is very small, compared with dy for all points $x + \Delta x$ in V_{δ}^* . Thus, in the immediate vicinity of x, the principal part of Δy is dy.

Differentials owe their importance to this fact.

2. To make the notation homogeneous, it is customary to replace Δx by another symbol, dx, in the expression for dy. We have then

$$dy = f'(x)dx$$
.

391. The notion of a differential may be illustrated as follows: Let the graph of f(x) be that in the figure.

Let PR be the tangent at P; and

$$PS = \Delta x$$
, $QS = \Delta y$, $RS = dy$.

Then

$$QR = \epsilon' \Delta x.$$

The reader will see, if $dy \neq 0$, that as Q approaches P, QR becomes smaller and smaller as compared with RS = dy. This is illustrated by comparing this ratio at Q and at Q'.

We see dy = RS approximates more and more closely to Δy as Q approaches P.

392. A variable whose limit is 0 is called an infinitesimal.

When employing differentials, we suppose that the increment given to the independent variable $\Delta x = dx$ can be taken as small, numerically, as we choose. It is thus an infinitesimal. Then both Δy and dy are also infinitesimals.

In the limits considered in 301-304, 310-312, the numerators and denominators furnish examples of infinitesimals.

Also the lengths of the intervals considered in 127, 2, are infinitesimals.

Many other examples of infinitesimals are to be found in the preceding pages, and many more will occur in the following.

The Law of the Mean

333 One of the pillars which support the modern rigorous development of the criterius is the Law of the Mean It rests on Rolle's Theorem Let f(x) be continuous in $\mathfrak{A} = (a \ b)$ and f(a) = f(b) Let f'(x) be finite or infinite within \mathfrak{A} . Then there

exists a point c within A for which
$$f(c) = 0 \qquad a < c < h$$

Since f(x) is continuous in $\mathfrak A$ it is limited by 350. Its extremes are therefore finite. If f is not constant, one of these extremes is different from the end values

To fix the ideas let $Max f = \mu$ be different from the end values By 354 there is a point c within A such that

$$f(c) = \mu$$

while for all points $c + \lambda$ of $\Re \lambda > 0$

$$f(c+h)-f(c)\leq 0 \quad f(c-h)-f(c)\leq 0$$

Hence

$$\frac{f(c+h)-f(c)}{h} \le 0, \tag{1}$$

$$\frac{f(e-h)-f(e)}{b} \ge 0 \tag{}$$

According to 1) $f'(c) \ge 0$;

according to 2),

f(o) > 0Those together require that

1 noso together require that

$$f(e)=0$$

In case f(x) is a constant in $\mathfrak A$ the theorem is obviously true

394 1 The geometric interpretation of Rolle's theorem is the following

Let the graph of f(x) be a con-

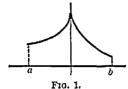

Let the graph of f(x) be a continuous curve having everywhere a tangent except possibly at the

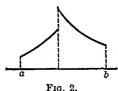

end points A, B, which are at the same height above or below the x-axis. Then at some point C the tangent is parallel to the x-axis.

Since f'(x) may be infinite, the graph may have points of inflection with vertical tangents, as at P.

- 2. Let A, B be two points at the same height above the x-axis. The reader will feel the truth of Rolle's theorem for simple cases if he tries to draw a continuous curve Γ through A, B, whose tangent is not parallel to the x-axis. Γ should, of course, have no vertical cusp or angular point. We say for simple cases, because we cannot draw a curve with an infinite number of oscillations or a curve which does not have a tangent at A or B. Yet neither of these cases need to be excluded in Rolle's theorem.
- 395. If f'(x) does not exist for some point within \mathfrak{A} , the theorem 394 is not necessarily true, as Fig. 1 shows. (See 366.)

If f'(x) is not continuous in \mathfrak{A} , the theorem does not need to be true, as Fig. 2 shows.

- 396. 1. Criticism. Many demonstrations are rendered invalid because they rest on the assumption:
- 1°. In passing from a to b, the function must first increase and then decrease, or first decrease and then increase;

or on the assumption:

2°. There must be at least one point between a, b where the function ceases to increase and begins to decrease, or conversely.

Either of these assumptions is true if we use functions having only a finite number of oscillations in A.

In case the function has an infinite number of oscillations in A. neither of the above assumptions need be true.

The function of Ex 2, 378, where $\mathfrak{A}=\ell 0, 1$), illustrates the untruth of 1°

We shall later exhibit functions which oscillate infinitely often in any little interval of M and yet have a derivative in M Such functions show that 2° is not always correct

- 2 The demonstration given in 393 is extremely simple. It rests, however, on the property that a continuous function takes on its extreme values in an interval (σ δ). In an elementary treatise this fact might be admitted without proof since it seems so obvious.
- 397 1 Law of the Mean Let f(x) be continuous in $\mathfrak{A} = (a,b)$, and let f'(x) be finite or infinite within \mathfrak{A}

Then for some point a < e < b

$$f(b) - f(a) = (b - a)f'(c)$$
 (1)

Consider the auxiliary function

$$g(z) = f(b) - f(z) - \frac{f(b) - f(a)}{b - a}(b - z)$$

Evidently

$$g(a) = g(b) = 0$$

Also at those points, at which f'(z) is finite,

$$g'(z) = -f'(z) + \frac{f(b) - f(a)}{b - a},$$
 (2)

while at the other points of \mathfrak{A} g'(x) is infinite. Thus g(x) is continuous in \mathfrak{A} and g'(x) is finite or infinite within \mathfrak{A} . Hence, for some point a < c < b,

$$g'(c) = 0$$
, by 393 (3)

Setting $x = \varepsilon$ in 2), and using 3) we get

$$f'(c) = \frac{f(b) - f(a)}{b - a}, \tag{4}$$

which is 1)

2. The relation 1) is commonly written as follows:

Set
$$b-a=h$$
;

then, since c lies within (a, b),

$$c = a + \theta h$$
, $0 < \theta < 1$.

Thus 1) gives
$$c = a + \theta h. \qquad 0 < \theta < 1.$$

$$f(a+h) = f(a) + hf'(a+\theta h).$$

- 3. The reader should observe that although f'(x) may be infinite within \mathfrak{A} , the point c in 1) is such that f'(c) is finite.
- 398. The following is the geometric interpretation of the Law of the Mean. Let ACB be the graph of f(x) in \mathfrak{A} . Let the chord AB make the angle θ with the x-axis. Then

$$\tan \theta = \frac{f(b) - f(a)}{b - a}.$$

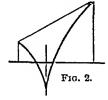

Also by 397, 4),

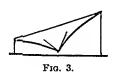

$$f'(c) = \tan \theta$$
.

That is: at some point c within the interval (a, b) the tangent is parallel to the chord AB.

399. When either of the conditions that enter the Law of the Mean are violated, the point c may not exist. This is illustrated by the following.

- 1. f(x) is not continuous in (a, b). Fig. 1.
- 2. The differential coefficient does not exist at some point within (a, b). Figs. 2, 3.

400 We give now some elementary applications of the Law of the Mean

1 Let f(x) be continuous in $\mathfrak{A} = (a, b)$, and let its derivative $f'(x) = \lambda$, a constant, within \mathfrak{A} . Then

$$f(x) = \lambda x + \mu$$
, in \mathfrak{A} (1)

Let x > a be a point of \mathfrak{A} The function f(x) satisfies the conditions of the Law of the Mean in $\mathfrak{R} = \{a, x\}$

Hence, by 397,

$$f(x) = f(a) + (x - a)f'(c), \quad a < c < x. \quad (2)$$

Since by hypothesis,

$$f'(c) = \lambda$$

we get 1) from 2), on setting

$$\mu = f(a) - af'(c)$$

Since, by hypothesis, f(x) is continuous, the formula 1) is also true for x = a

2. As a corollary of I we have

Let f(x) be consinuous in $\mathfrak{A} = (a \ b)$ and let its derivative be 0 within \mathfrak{A} . Then f(x) is a constant in \mathfrak{A} .

3 Let f(x), g(x) be continuous in the interval A, and let f'(x) = g'(x) within A. Then, C being some constant,

f(x) =

$$f(x) = g(x) + C, \quad \text{in } \mathbb{I}$$
 (3)

$$k(x) = f(x) - g(x)$$

satisfies the conditions of 2 Hence

$$k(x) = C_1$$
 in \mathfrak{A}

401 Let f(x) be continuous in N = (a, b), while f'(x) is finite or infinite within N Let f'(x), when not 0, have one u, n σ. Then f is monotone increasing in X, if σ is positive, monotone decreasing, if σ is negative.

Let
$$a < x^{i} < x^{ii} \le b$$

By the Law of the Mean,

$$f(x'') = f(x') + (x'' - x')f'(c).$$
 $x' < c < x''.$

As x'' - x' > 0, and f'(c) has the sign σ , when not 0,

$$f(x'') \ge f(x')$$
, if σ is positive; $f(x'') \ge f(x')$, if σ is negative.

402. Criticism. Some writers state that f(x) is increasing when f'(x) is positive, and conversely when f(x) is increasing f'(x) is positive.

The second statement is not true, as the figure shows. P is a point of inflection, with a tangent parallel to the x-axis.

The error in the reasoning is instructive. By definition, if f(x) is increasing,

 $\frac{\Delta f}{\Delta x}$

is positive. It is now inferred that therefore

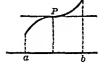

$$\lim \frac{\Delta f}{\Delta x} = f'(x)$$

is positive. All one can strictly infer is that $f'(x) \equiv 0$.

The function

$$y=x^3, \qquad \mathfrak{A}=(-1,1)$$

illustrates this, at the point x = 0. See Fig.

403. Let f(x) be continuous in $\mathfrak{A} = (a, b)$, and f'(x) finite or infinite within \mathfrak{A} . f'(x) shall not vanish for all the points of any subinterval $\mathfrak{B} = (\alpha, \beta)$ of \mathfrak{A} . When not 0, let f'(x) have always one sign σ in \mathfrak{A} . Then f(x) is an increasing or a decreasing function in \mathfrak{A} , according as σ is positive or negative.

To fix the ideas, let σ be positive.

Let
$$a \le x' < x'' \le b$$
.

By the Law of the Mean,

$$f(x'') = f(x') + (x'' - x')f'(c)$$
. $x' < c < x''$.

As $x^{ij} - x^{i} > 0$, and $f'(\epsilon) \ge 0$, we have

t e, f(x) is monotone increasing in $\mathfrak A$. To show it is constantly increasing in $\mathfrak A$, suppose

$$f(\alpha) = f(\beta)$$

Then f(x) must = f(a) for all points in $\mathfrak{B} = (a, \beta)$, since it is a monotone increasing function

Since f(x) is a constant in $\mathfrak{B} f'(x) = 0$ in \mathfrak{D} which contradicts the hypothesis

404 Let f'(x) be continuous in the interval A. Then the difference quotient $\frac{\Delta y}{L}$ converges uniformly to f'(x) in A.

For, by the Law of the Mean

$$f(x+h)-f(x)=hf'(x+\theta h) \qquad 0<\theta<1$$

Hence

$$\frac{\Delta y}{\Delta x} = f'(x + \theta h) \tag{1}$$

But f'(x) being continuous in \mathfrak{A} , is uniformly continuous by 352. Hence

$$\lim_{k\to 0} f'(z+\theta k) = f'(z) \quad \text{uniformly}$$

Hence by 1),

$$\lim \frac{\Delta y}{\Delta z} \approx f'(z) \quad uniformly in X$$

Derivatives of Higher Order

405 The first derivative of f'(x) is called the second derivative of f(x) and is denoted by

$$f''(x) D_x^x f(x) \frac{d^2f}{dx^2}$$

Evidently,

$$f''(x) = \lim_{\lambda \to 0} \frac{f'(x+h) - f'(x)}{h} = \lim_{\lambda \to 0} \frac{\Delta f'(x)}{\Delta x},$$

this limit being finite or infinite

In this way we may continue to form third, fourth, ... and derivatives of any order.

Derivatives of order n are denoted by

$$f^{(n)}(x), D_x^n f(x), \frac{d^n f}{dx^n}$$

406. We add the following formulæ, which will be used later. They are easily verified:

$$D_x^n x^{\mu} = \mu \cdot \mu - 1 \cdot \dots \cdot \mu - n + 1 \cdot x^{\mu - n}. \qquad x > 0.$$
 (1)

$$D_x^n(1+x)^{\mu} = \mu \cdot \mu - 1 \cdot \dots \mu - n + 1 \cdot (1+x)^{\mu-n}. \quad 1+x>0.$$
 (2)

$$D_x^n e^x = e^x. (3)$$

$$D_x^n \sin x = \sin\left(\frac{n\pi}{2} + x\right). \tag{4}$$

$$D_x^n \cos x = \cos\left(\frac{n\pi}{2} + x\right). \tag{5}$$

407. Let y = uv, where u, v have derivatives of any desired order. The following relation is known as Leibnitz's formula.

$$y^{(n)} = u^{(n)}v + \binom{n}{1}u^{(n-1)}v' + \binom{n}{2}u^{(n-2)}v'' + \cdots + \binom{n}{2}u''v^{(n-2)} + \binom{n}{1}u'v^{(n-1)} + uv^{(n)},$$
 (1)

where

$$\binom{n}{m} = \frac{n \cdot n - 1 \cdot \dots \cdot n - m + 1}{1 \cdot 2 \cdots m}.$$

We prove it by complete induction; i.e. we assume it true for n and prove it is true for n+1. For n=1, 2 it is obviously true. Differentiating 1), we get

$$y^{(n+1)} = u^{(n+1)}v + \binom{n}{1}u^nv^l + \binom{n}{2}u^{(n-1)}v^{ll} + \binom{n}{3}u^{(n-2)}v^{lll} + \cdots + u^{(n)}v^l + \binom{n}{1}u^{(n-1)}v^{ll} + \binom{n}{2}u^{(n-2)}v^{lll} + \cdots$$
 (2)

Now, by 96,

$$\binom{n}{m} + \binom{n}{m-1} = \binom{n+1}{m}$$

This in 2), gives

$$y^{(n+1)} = u^{(n+1)} v + \binom{n+1}{1} u^{(n)} v' + \binom{n+1}{2} u^{(n-1)} v'' + \cdots$$

which is 1), when we replace in it n by n+1.

408 1 Let us apply Leibnitz's formula to find the derivatives of $u = f(x) = \tan x$.

We have

$$y'=\sec^2x,$$

 $y'' = 2 \sec^2 x \tan x = 2 y y'.$

Now

$$D_x^n(yy') = y^{(n+1)}y + \binom{n}{1}y^{(n)}y' + \binom{n}{2}y^{(n-1)}y'' + \cdots$$

This gives

$$y^{t''} = 2(y''y + y'^2),$$

$$y^{t''} = 2(y'''y + 3y'y'^2);$$

$$y'' = 2(y'''y + 4y''''y' + 3y'''^2)$$
, etc.

2 Another way is the following, which will lead us to a formula that we shall need late:

We have

$$y \cos x = \sin x$$

or setting.

u = yz

Now by Leibnitz's formula,

$$u^{(n)} = y^{(n)}z + {n \choose 1}y^{(n-1)}z^{g} + {n \choose 2}y^{(n-2)}z^{1f} + \cdots$$

а

Also, by 406, 4), 5),

$$u^{(n)} = \sin\left(\frac{n\pi}{2} + x\right), \ z^{(n)} = \cos\left(\frac{n\pi}{2} + x\right).$$

Hence 1) gives

$$\sin\left(\frac{n\pi}{2} + x\right) = \left\{y^{(n)} - \binom{n}{2}y^{(n-2)} + \binom{n}{4}y^{(n-4)} - \cdots\right\} \cos x$$
$$-\left\{\binom{n}{1}y^{(n-1)} - \binom{n}{3}y^{(n-2)} + \binom{n}{5}y^{(n-5)} - \cdots\right\} \sin x.$$

This gives the recursion formula,

$$y^{(n)} = \frac{\sin\left(\frac{n\pi}{2} + x\right)}{\cos x} + \binom{n}{2}y^{(n-2)} - \binom{n}{4}y^{(n-4)} + \cdots + \tan x \left\{ \binom{n}{1}y^{(n-1)} - \binom{n}{3}y^{(n-3)} + \cdots \right\}.$$
 (2)

Setting x = 0 in 2), we get

$$f^{(n)}(0) - \binom{n}{2} f^{(n-2)}(0) + \binom{n}{4} f^{(n-4)}(0) - \dots = \sin \frac{n\pi}{2}.$$
 (3)

Taylor's Development in Finite Form

409. 1. Using derivatives of higher order, we can generalize the Law of the Mean as follows:

In the interval $\mathfrak{A} = (a, b)$, let f(x) and its first n-1 derivatives be continuous. Let $f^{(n)}(x)$ be finite or infinite within \mathfrak{A} . Then for any x in \mathfrak{A} ,

$$f(x) = f(a) + \frac{(x-a)}{1!} f'(a) + \cdots + \frac{(x-a)^{n-1}}{n-1!} f^{(n-1)}(a) + \frac{(x-a)^n}{n!} f^{(n)}(c),$$
 (1)

where

As in 397, we introduce an auxiliary function (x-u)

$$g(u) = f(x) - f(u) - (x - u)f'(u) - \frac{(x - u)^3}{2^{\frac{1}{2}}} f''(u) - \cdots$$

 $-\frac{(x - u)^{n-1}}{2^{\frac{n}{2}}} f^{n-1}(u) - \frac{(x - u)^{n-1}}{2^{n-1}} A,$ (2)

where A is independent of u. This function is obviously a continuous function of u in $\mathfrak A$ for any x in $\mathfrak A$. Differentiating with respect to u, we get, observing terms cancel in pairs,

$$g'(u) = \frac{(x-u)^{n-1}}{n-1!} \{-f^{(a)}(u) + A\},\tag{3}$$

for any u within M

Thus the derivative of g(u) is finite within I

To apply Rolle's theorem to g(u), with reference to the interval $\mathfrak{B} = (a \ x)$, it is only necessary to determine A in 2) so that

But obviously

$$g(a) = g(x)$$

Par againagely

$$g(x)=0$$

We therefore suppose A so chosen that

$$0 = f(x) - f(a) - (x - a)f'(a) - \cdot - \frac{(x - a)^{n-1}}{n - 1!} f^{(n-1)}(a) - \frac{(x - a)^n}{n!} A,$$
 (4)

Then by Rolle's theorem, there is a point a < c < x, such that

$$g'(c) = 0$$

This in 3) gives

$$\frac{(z-c)^{n-1}}{n-1}|f^{(n)}(c)-A|=0$$
 (5)

As $c \neq x$, the first factor in 5) is not 0. Hence the parenthesis is 0, which gives

 $f^{(s)}(c) = A$

Putting this value of A in 4), we have 1)

2. The formula 1) is called Taylor's development of f(x) in finite form.

It may also be written as follows:

Set.

$$x = a + h$$
, $c = a + \theta h$. $0 < \theta < 1$.

Then 1) becomes

$$f(a+h) = f(a) + \frac{h}{1!} f'(a) + \frac{h^2}{2!} f''(a) + \cdots$$

$$+ \frac{h^{n-1}}{n-1!} f^{(n-1)}(a) + \frac{h^n}{n!} f^{(n)}(a+\theta h).$$

$$(6)$$

$$a+h, in \Re.$$

410. 1. Let f(x) and its first n-1 derivatives be continuous in the interval $\mathfrak{B} = (a-H, a+H)$, while $f^{(n)}(x)$ is finite in \mathfrak{B} . Then for any x in \mathfrak{B} ,

$$f(x) = f(a) + \frac{(x-a)}{1!} f'(a) + \frac{(x-a)^2}{2!} f''(a) + \cdots$$

$$+ \frac{(x-a)^{n-1}}{n-1!} f^{(n-1)}(a) + \frac{(x-a)^n}{n!} f^{(n)}(c), \qquad (1$$

$$= f(a+h) = f(a) + \frac{h}{1!} f'(a) + \frac{h^2}{2!} f''(a) + \cdots$$

$$+ \frac{h^{n-1}}{n-1!} f^{(n-1)}(a) + \frac{h^n}{n!} f^{(n)}(a+\theta h), \qquad (2$$

where

$$x=a+h$$
, $c=a+\theta h$, $0<\theta<1$, $|h|\leq H$.

The truth of this theorem for the left hand half of \mathfrak{B} follows from the fact that the reasoning of 409 does not depend upon a being < b; it holds when a > b, if we change x and c accordingly.

2. When a = 0, 1) gives

$$f(x) = f(0) + \frac{x}{1!} f'(0) + \frac{x^2}{2!} f''(0) + \dots + \frac{x^n}{n!} f^{(n)}(\theta x).$$
 (3)

This is known as Maclaurin's development,

411 1 Let
$$f(x) = \sin x$$

From 410, 3) we get

$$\sin x = x - x^2 \frac{\sin \theta x}{91}$$

 $=x-\frac{x^3}{3!}+\frac{x^4}{3!}\sin\theta x, \quad 0<\theta<1$

$$= x - \frac{x^3}{5!} + \frac{x^5}{5!} - \frac{x^4}{5!} \sin \theta x,$$

The f a in these formulæ are not necessarily the same. Let $0 < x < \frac{\pi}{6}$

These formulæ show then that

810 x < x

etc

$$> x - \frac{x^2}{3!}$$

$$< x - \frac{x^3}{31} + \frac{x^3}{51},$$

From 1) we have again

$$\lim_{n \to \infty} \frac{\sin x}{n} = 1 - \lim_{n \to \infty} x \cdot \frac{\sin \theta x}{n} = 1.$$

See 301

As before, we get

$$f(x) = \cos x$$

$$\cos x < 1$$

$$>1-\frac{x^2}{2!},$$
 $0< x<\frac{\pi}{2}$ $<1-\frac{x^2}{2!}+\frac{x^4}{4!},$

 α

etc

$$\cos x = 1 - \frac{x^2}{91} + \frac{x^2}{91} \sin \theta x,$$

From

we have

$$\lim_{x=0} \frac{1 - \cos x}{x^2} = \frac{1}{2} - \frac{1}{3!} \lim_{x=0} x \sin \theta x$$
$$= \frac{1}{2}.$$

See 304.

413. 1. Let

$$f(x) = \log (1+x).$$

From 410, 3) we get

$$\log (1+x) = x - \frac{x^2}{2!} \frac{1}{(1+\theta x)^2}$$
 $0 < \theta < 1$.

Hence, as in 310,

$$\lim_{x \to 0} \frac{\log(1+x)}{x} = 1.$$

2. Let

$$f(x) = a^x. \qquad a > 0.$$

From 410, 3) we have

$$a^{x} = 1 + \frac{x}{1!} \log a + \frac{x^{2}}{2!} \log^{2} a \cdot a^{\theta x}, \quad 0 < \theta < 1.$$

Hence, as in 311,

$$\lim_{x\to 0}\frac{a^x-1}{x}=\log a.$$

3. Let

$$f(x) = (1+x)^{\mu}.$$

We get from 410, 3)

$$(1+x)^{\mu} = 1 + \mu x + x^{2} \cdot \frac{\mu \cdot \mu - 1}{2} (1+\theta x)^{\mu-2}.$$
 $|x| < 1, \ 0 < \theta < 1.$

Hence, as in 312,

$$\lim_{x \to 0} \frac{(1+x)^{\mu} - 1}{x} = \mu.$$

FUNCTIONS OF SEVERAL VARIABLES

Partial Differentiation

414. The definition of a partial differential coefficient and a partial derivative of a function of several variables is analogous to the corresponding definitions for functions of a single variable.

Let $f(x_1 \cdots x_n)$ be defined over a domain D, for which $x = (x_1 \cdot x_n)$ is a proper limiting point

Let $x' = (x_1 \cdot x_{i-1}, x_i + h, x_{i+1} \cdot x_m)$ be any point of D, different from x. If

 $\eta = \lim_{h \to 0} \frac{f(x') - f(x)}{h} \tag{2}$

is finite or infinite, it is called the (first) partial differential coefficient of f unit respect to x, at the point x. The aggregate of these η 's defines a new function over a certain domain $\Delta \in D$, which is called the (first) partial derivative of f with respect to x.

It is denoted variously by

$$D_{x_i}f(x_1 - x_n), \frac{\partial f(x_1 - x_n)}{\partial x}, f_{x_i}(x_1 - x_n).$$
 (2)

When h in 1) is restricted to positive values, n is called a right hand partial differential coefficient, and their aggregate gives rise to the right hand partial derivative with respect to z.

The meaning of the terms left hand partial differential coefficient and derivative with respect to z. is obvious

and derivative with respect to x, is obvious

They are denoted by putting the letters R and L before the symbols 2)

The function $f(x_1 x_n)$ has therefore in general m (first) partial derivatives.

$$\frac{\partial f}{\partial x_1}$$
, $\frac{\partial f}{\partial x_2}$, $\frac{\partial f}{\partial x_3}$

The process of obtaining these partial derivatives is called partial differentiation

415 FRANCE

$$f(xy) = \sqrt{x^1 + y^1}$$

If the point x, y is not at the origin,

We can therefore apply 3"8 and 387, getting

$$\frac{\partial f}{\partial x} = \frac{x}{\sqrt{x^2 + y^2}} \cdot \frac{\partial f}{\partial y} = \frac{y}{\sqrt{x^2 + y^2}}$$

Thus the partial derivatives with respect to z and y exist at all points different from the origin When the point x, y is at the origin, we cannot apply this method. (Compare 388.)

We therefore proceed directly. We have

$$\frac{\Delta f}{\Delta x} = \frac{\sqrt{\Delta x^2}}{\Delta x}$$

This shows that

$$Rf'_x(0, 0) = +1$$
, $Lf'_x(0, 0) = -1$.

Thus the partial differential coefficient with respect to x does not exist at the origin. Similarly,

$$Rf_y(0, 0) = +1, Lf_y(0, 0) = -1;$$

and the partial derivative with respect to y does not exist at the origin.

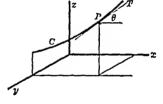

416. In the case of two independent variables, the (first) partial differential coefficients admit a simple geometric interpretation.

Let the graph of

$$z = f(x, y)$$

be a surface S. The plane

$$y = constant$$

intersects S in a curve C.

Let PT be the tangent to C at P = (x, y, z), making the angle θ with the x-axis. Then

$$\frac{\partial f}{\partial x} = \tan \theta.$$

Compare 365.

The partial differential coefficient

$$\frac{\partial f}{\partial y}$$

has a similar meaning with respect to the y-axis.

417. Let $f'_{x_i}(x_1 \cdots x_m)$ be finite for a domain Δ . We may now eason on f'_{x_i} as we did on f. Let x be a proper limiting point of f, and $f'_{x_i} = (x_1 \cdots x_{j-1}, x_j + h, x_{j+1} \cdots x_m)$ any point of Δ different from f.

$$\lim_{t\to 0}\frac{f'_{x_i}(x')-f'_{x_i}(x)}{h}=\eta$$

is finite or infinite, η is called the second partial differential coefficient of f with respect to x, x, at the point x, and is denoted by

$$D^2_{x,s,f}(x_1-x_n), \frac{\partial^2 f(x_1-x_n)}{\partial x}, f'_{x,s,j}(x_1-x_n)$$

The aggregate of these η 's will define a new function over a certain domain $\Delta_1 \not \equiv \Delta$, which is called the second partial derivative, first with respect to x, then with respect to x,

Proceeding in this way, we may form third, fourth, partial differential coefficients and derivatives

Change in the Order of Differentiating

416 1 In almost all cases which occur in practice, the partial differential coefficient has the same value, however the order of differentiation is chosen. For example

$$f_{s,s,s}^{(i)} = f_{s,s,s}^{(i)} = f_{s,s,s}^{(i)} = f_{s,s,s}^{(i)} = f_{s,s,s}^{(i)} = f_{s,s,s}^{(i)}$$

That this is not always true is shown by the following example

2
$$f(x, y) = xy \frac{x^2 - y^2}{x^2 + y^2}$$
 for points different from the origin

Then if x, y is not the origin,

$$\frac{\partial f}{\partial x} = y \left\{ \frac{x^2 - y^2}{x^2 + y^2} + \frac{4x^2y^2}{(x^2 + y^2)^2} \right\},\tag{1}$$

$$\frac{\partial f}{\partial y} = x \left\{ \frac{x^2 - y^2}{x^2 + y^2} - \frac{4 x^2 y^2}{(x^2 + y^2)^2} \right\}. \tag{2}$$

At the origin,

$$\frac{\partial f}{\partial x} = 0, \quad \frac{\partial f}{\partial y} = 0 \tag{3}$$

.,

From 1), 2) we have, in particular,

$$f'_{\tau}(0,y) = -y, y \neq 0;$$
 (4)

$$f_{\nu}'(x,0) = x, \quad x \neq 0.$$
 (5)

Consider now the second partial derivatives.

From 1), 2) we have, for all points different from the origin,

$$\frac{\partial^2 f}{\partial x \partial y} = \frac{x^2 - y^2}{x^2 + y^2} \left\{ 1 + \frac{8 \, x^2 y^2}{(x^2 + y^2)^2} \right\} = \frac{\partial^2 f}{\partial y \partial x}.$$

At the origin, we have from 3), 4), 5),

$$\frac{\Delta f_x'}{\Delta y} = -\frac{\Delta y}{\Delta y}; \quad \therefore f_{xy}''(0,0) = -1. \tag{6}$$

$$\frac{\Delta f_y'}{\Delta x} = \frac{\Delta x}{\Delta \dot{x}}; \quad \therefore f_{yx}''(0,0) = +1. \tag{7}$$

Hence, at the origin,

$$\frac{\partial^2 f}{\partial x \partial y} \neq \frac{\partial^2 f}{\partial y \partial x}.$$

3. In connection with this example, we may warn the inexperienced reader to avoid certain errors he is likely to fall into.

To get the equations 3), i.e.

$$f'_x(0,0) = 0, f'_y(0,0) = 0,$$

it is not permissible to set x = 0, y = 0 in the relations 1), 2). In fact, these formulæ were obtained under the express stipulation that this point x = y = 0 be ruled out.

To get the equation 6), i.e.

$$f_{xy}^{\prime\prime}(0,0) = -1, \tag{6}$$

it is not permissible to differentiate 4), i.e.

$$f_x^l(0,y) = -y,$$
 (4)

with respect to y, thus getting

$$f_{xy}^{(l)}(0,y) = -1;$$

and in this set y = 0, getting the required value of $f_{xy}^{\prime\prime}(0,0)$.

In fact, the relation 4) was obtuned under the express condition that $u \neq 0$

Similar remarks apply to f''(0,0)

Junior students are so accustomed to differentiate with their eyes shut that they often overlook the fact that formulae and theorems are usually not universally true, but are subject to more or less stringent conditions. Compare also the example of 388. 4

419 It is easy to see a priors why $f_{xy}^{\prime\prime}(a,b)$ may be different from $f_{xy}^{\prime\prime}(ab)$

By definition,

$$\begin{split} f'_{t}(\alpha, y) &= \lim_{k \to 0} \frac{f(\alpha + k, y) - f(\alpha, y)}{k}, \\ f''_{t}(\alpha, b) &= \lim_{k \to 0} \frac{f_{t}(\alpha, b + k) - f'_{t}(\alpha, b)}{k} \\ &= \lim_{k \to 0} \frac{1}{k} \left[\lim_{k \to 0} \frac{f(\alpha + k, b + k) - f(\alpha, b)}{k} \right] \\ &- \lim_{k \to 0} \frac{f(\alpha + k, b) - f(\alpha, b)}{k} \right] \end{split}$$

Let us set

$$F(h,k) = \frac{f(a+h,b+k) - f(a,b+k) - f(a+h,b) + f(a,b)}{hk}.$$

Then 1) gives

$$f_{s_2}^{\prime\prime}(a,b) = \lim_{b\to 0} \lim_{b\to 0} F(b,k)$$

In a similar manner we find *hat

$$f_{yx}^{\prime\prime}(a,b) = \lim_{k \to 0} \lim_{k \to 0} F(h,k)$$

These formulæ show that $f_{ss}^{**}(a,b) f_{ss}^{**}(a,b)$ are double iterated limits, taken in different order. It is therefore not astonishing that a change in the order of passing to the limit may produce a change in the result. Cf. 322, 323.

420. 1. We consider now certain eases when it is possible to change the order of differentiation in a partial differential coefficient.

Let f(xy) be defined in D(a, b). Let D^* be the deleted domain of D. We suppose:

a) that f'_x exists in D,

 β) that f_{xy}^{11} exists in D^* ,

 γ) that $\lim_{x\to a, y\to b} f''_{xy} = \lambda$. finite or infinite.

Then

$$f_{xy}^{\prime\prime}(a,b) = \lambda. \tag{1}$$

If, moreover,

 δ) f'_{y} exists for all points of D on the line y = b; then

$$f_{yx}^{\prime\prime}(a,b) = \lambda. \tag{2}$$

We suppose first, that all four conditions $\alpha-\delta$ are satisfied, and show that then $f_{xy}^{ij}(a,b) = f_{yx}^{ij}(a,b). \tag{2}$

Let

$$F = \frac{f(a+h, b+k) - f(a, b+k) - f(a+h, b) + f(ab)}{hk},$$

as in 419. We introduce the auxiliary functions

$$G(x) = f(x, b+k) - f(x, b),$$
 (3)

$$H(y) = f(a + h, y) - f(a, y).$$
 (4)

Then

$$hkF = G(a+h) - G(a)$$
 (5)

$$=H(b+k)-H(b). (6)$$

Setting, as usual,

$$h = \Delta x, \quad k = \Delta y,$$

we have from δ),

$$\left|\frac{\Delta f}{\Delta y} - f_y'(x,b)\right| = \epsilon(x);$$

where $\epsilon = \epsilon(x)$ is a function of k and x, such that

$$\lim_{\epsilon \to 0} \epsilon = 0. \tag{7}$$

$$G(x) = \Delta f = k \left\{ f_{\bullet}(x \ b) + \epsilon(x) \right\} \tag{8}$$

Similarly by a)

$$H(y) = h\{f_s(a \ y) + \eta(y)\},\,$$

where $\eta = \eta(y)$ is a function of A and y such that

$$\lim_{n\to\infty}\eta=0$$

(9

(10

Then 5) 8) give

$$F = \frac{1}{4} \{ f_{\mathbf{v}}^{\prime}(a + h \ b) - f_{\mathbf{v}}(a \ b) + \epsilon(a + h) - \epsilon(a) \}$$
 (11)

Similarly 61 9) give

$$F = \frac{1}{k} \{ f_s(a \ b + k) - f_s(a \ b) + \eta(b + k) - \eta(b) \}$$
 (12)

On the other hand we can apply the Law of the Mean to 5) by virtue of a) getting

$$kF - G(c)$$
 $a < c < a + h$ or $a + h < c < a$ (18)

Differentiating 3) we get using 13)

$$kF = \{f_s^*(c \ b + k) - f_s^*(c \ b)\}\$$
 (14)

By virtue of β we can apply the Law of the Venn to $F - f'_{-}(c d)$ b < d < b + k or b + k < d < b

From 11) 15) we have

$$f'_{sp}(c \ d) = \frac{f_s(a + h \ b) - f'_p(a \ b)}{h} + \frac{\epsilon(a + h)}{h} - \frac{\epsilon(a)}{h}$$
 (16)
From 12) 15) we have

$$f_{D}^{i}(c|\vec{a}) - \frac{f_{s}^{i}(a|\vec{b}+k) - f_{s}^{i}(ab)}{k} + \frac{\eta(b+k)}{k} - \frac{\eta(b)}{k}$$
 (17)

We can now apply 324 to 16) Now by y)

$$\lim f_{xy}(c \ d) = \lambda.$$

By 7)
$$\lim_{k=0} \epsilon(a+h) = 0, \lim_{k=0} \epsilon(a) = 0.$$

Hence, letting k first pass to the limit, and then h,

$$\lambda = \lim_{h \to 0} \lim_{h \to 0} \left[\frac{f'_{y}(a+h,b) - f'_{y}(ab)}{h} + \frac{\epsilon(a+h)}{h} - \frac{\epsilon(a)}{h} \right]$$

$$= \lim_{h \to 0} \frac{f'_{y}(a+h,b) - f'_{y}(ab)}{h}$$

$$= f''_{yx}(a,b). \tag{18}$$

Similarly, 17) gives, letting first h pass to the limit, and then k,

$$\lambda = f_{xy}^{\prime\prime}(a,b). \tag{19}$$

The equations 18), 19) prove 2').

- 2. If we wish to prove 1), without imposing the condition δ), we have only to observe that 17) has been established without reference to δ). But, as has just been shown, we can conclude 1) from 17).
- 3. It is well to note that this demonstration does not postulate the existence of $f_{yx}^{\prime\prime}$; or the continuity of either of the second partial derivatives; or the continuity of f_y^{\prime} in D or D^* .

We observe also that x and y can obviously be interchanged in the statement of the above theorem.

421. The case which ordinarily arises is embodied in the following corollary:

Let f'_x , f'_y , f'_{xy} be continuous in the domain of the point a, b. Then $f''_{yx}(a, b)$ exists, and is equal to $f''_{xy}(a, b)$.

422. It is easy to generalize 421 as follows:

Let the partial derivatives of $f(x_1 \cdots x_m)$ of order $\geq n$ be continuous in the domain of the point x. Then we can permute the indices ι in

$$f_{x_1,x_2,\cdots x_m}^{(n)}(x_1\cdots x_m), \qquad (1$$

without changing its value.

Since any permutation of the n indices

can be obtained from any other permutation

by repeated interchanges of successive indices, we have only to show that we can interchange any two successive indices as ι_{Q} ι_{c+1} in 1) without changing its value

Let us introduce the function of x. x.

$$g(x_{\omega}, x_{\omega_{n+1}}) = f_{x_1 \dots x_n}^{(r-1)}(x_1 - x_n),$$

where we consider all the variables on the right as fixed, except the two noted in g

Then, by 421,

$$\frac{\sigma^2 g}{\partial x_{i_1} \partial x_{i_{r+1}}} = \frac{\partial^2 g}{\partial x_{i_{r+1}} \partial x_{i_r}}$$

Hence

Differentiating now with respect to $x_{\omega_{0}}$ $x_{\omega_{0}}$ in the order given, we get

 $f_{z_{i_1} \ z_{i_2} f_{i_{2i_1}} \ z_{i_2}}^{(a)} = f_{z_{i_1} \cdots z_{i_{r-1}} z_{i_{r+1}} z_{i_{r'}} z_{i_{r'}}}^{(a)}$

Totally Differentiable Functions

423 1 If the function f(x) has a finite differential coefficient at x = x, we saw that

 $\Delta f = f'(a)h + \alpha h,$

where h is an increment of x_i and a is a function of h, such that

$$\lim_{n\to\infty} \alpha = 0$$

Under certain conditions, to be given later, an analogous theorem holds for functions of several variables. Let Δf be the increment that $f(z_1 - z_n)$ receives when we pass from the point $a = (a_1 - a_n)$ to the point $a + k = (a_1 + k_1 - a_n + k_n)$.

Here any of the h's may = 0. Let

$$\Delta f = f'_{x_1}(a)h_1 + \dots + f'_{x_m}(a)h_m + \alpha_1h_1 + \dots + \alpha_mh_m,$$

where the a_r are functions of $h_1 \cdots h_m$, such that

$$\lim_{n\to 0}\alpha_1=0, \quad \cdots \lim_{n\to 0}\alpha_m=0.$$

The function f is, in this case, said to be a totally differentiable function at a.

We call
$$df = f'_{x}(a)h_1 + \dots + f'_{x_n}(a)h_m \tag{1}$$

the total differential of f at a.

Thus, when f is totally differentiable at a, Δf consists of two parts, viz.: $df \quad \text{and} \quad \alpha, h_1 + \dots + \alpha_m h_m.$

Here the a's in the second part have the limit 0 when $h \doteq 0$. If we replace a by x and set $h_1 = dx_1, \dots h_m = dx_m, 1$ becomes

$$df = f'_{x_1}(x) dx_1 + \dots + f'_{x_m}(x) dx_m$$
$$= \frac{\partial f}{\partial x_1} dx_1 + \dots + \frac{\partial f}{\partial x_m} dx_m.$$

424. 1. It is easy to give examples of functions which are not totally differentiable at every point.

Ex. 1.

Consider

$$f(x, y) = \sqrt{|xy|} = \sqrt[4]{x^2y^2}$$

at the origin. Here

$$f'_x(0, 0) = 0, \quad f'_y(0, 0) = 0.$$

Hence

$$df = 0 (1$$

at the origin.

Suppose now f were totally differentiable at the origin. Then the increment Δf would, on account of 1), have the form

$$\Delta f = \alpha h + \beta k,\tag{2}$$

where the limits of α and β are 0.

This is not possible.

For, we have directly

$$\Delta f = f(h, k) - f(0, 0) = \sqrt{hk}$$
 (3)

From 2), 3) we have

$$\sqrt{|hk|} = \alpha h + \beta k$$
 (4

To show now that the hunts of α , β are not 0, let k, k=0,

running over the line L in the figure Then

h=ρcos θ k=ρsin θ θ constant

This in 4) gives

 $\rho\sqrt{\sin\theta\cos\theta} = \rho(\alpha\cos\theta + \beta\sin\theta)$ or

 $\sqrt{1} \sin 2\theta = a \cos \theta + \beta \sin \theta$ (5 If now -0 R-0

the limit of the right side of 5) is 0, while the limit of the left side depends on \$\theta\$ We are thus led to a contradiction

2 Ex 2

OF

$$f(xy) = \frac{xy}{\sqrt{x^2 + y^2}} \text{ for } x \text{ y not the origin.}$$

$$= 0, \text{ for the origin}$$

$$f''_x(0, 0) = \lim_{x \to \infty} \frac{f(k, 0) - f(0, 0)}{h} = 0$$

 $f_{t}'(0 \ 0) = 0$

 $\partial f = 0$

If now f were totally differentiable at the origin, at the onem we would have $\Delta f = ah + Bk$

 $\tau \cos \theta \sin \theta = \tau (\alpha \cos \theta + \beta \sin \theta)$ Hence

 $\cos \theta \sin \theta = \alpha \cos \theta + \beta \sin \theta$

Letting now k, k = 0, this gives, in the limit,

 $\cos \theta \sin \theta = 0$, which is absurd

425. Let f(xy) be defined in the domain D of the point P = (a, b). We suppose that:

a) f'_x exists in D, β) f'_y exists at P,

 γ) f'_{x} or f'_{y} is continuous at P.

Then f is totally differentiable at P.

For,

$$\Delta f = f(a+h, b+k) - f(a, b)$$

$$= \{ f(a+h, b+k) - f(a, b+k) \} + \{ f(a, b+k) - f(ab) \}$$

$$= \Delta_1 + \Delta_2.$$
(1)

By α) we can apply the Law of the Mean to Δ_1 , getting

$$\Delta_1 = h f_x'(c, b+k).$$
 $a < c < a+h \text{ or } a+h < c < a.$ (2)

By β) we have

$$\Delta_2 = k\{f_v'(a,b) + \beta\},\tag{3}$$

where β is a function of k, such that

$$\lim_{\delta \to 0} \beta = 0. \tag{4}$$

From 1), 2), 3) we have

 $\Delta f = h f_x'(c, b+k) + k \{ f_y'(ab) + \beta \}.$

Set

$$\alpha = f_x'(c, b + k) - f_x'(a, b).$$
 (5)

Then

$$\Delta f = h f_x'(ab) + k f_y'(a, b) + \alpha h + \beta k. \tag{6}$$

By
$$\gamma$$
), $\lim_{n \to \infty} \alpha = 0$. (7)

Equations 6), 4), 7) show that f is totally differentiable at P.

- 426. 1. Under less general conditions we can generalize 425 as follows:
- a) Let $f(x_1 \cdots x_m)$ be defined over the domain D, of the point x; and have finite partial derivatives $f'_{x_1} \cdots f'_{x_m}$ in D.
 - β) Let f'_{x_n} be a continuous function of x_n , $x_{n+1} \cdots x_m$.

$$\kappa=1, 2 \cdots m.$$

Then f is totally differentiable at x.

To fix the ideas, take m = 3 We have, setting for brevity. $x_1 = x_1 + h_1$ $x_2 = x_2 + h_2$, $x_3 = x_2 + h_3$,

$$\Delta f = f(\bar{x}_1 \bar{x}_2 x_4) - f(x_2 x_2 x_4) = \{ f(x_1 x_2 x_4) - f(x_1 \bar{x}_2 x_4) \}$$

$$+ \{ f(x_1 x_2 x_4) - f(x_1 x_2 x_4) \} + \{ f(x_1 x_2 \bar{x}_4) - f(x_1 x_2 x_4) \}$$

 $=\Delta_1 + \Delta_2 + \Delta_3$

By virtue of s) we can apply the Law of the Mean to each of these A s, getting

 $\Delta_1 = h_1 f'_1(x_1 + \theta_1 h_1 x_2 x_3),$ (1 (2

(8

(4

6

(6

Then

rm) be continuous in

 $\Delta_t = h_s f_s(x_1, x_2 + \theta_s h_s, x_s),$ $\Delta_1 = h_2 f_{t_0}'(x_1 \ x_2, x_3 + \theta_2 h_2)$

Making use of \$1 we may write 1), 2) 3)

 $\Delta_1 = h_1 f_0'(x_1 x_2 x_2) + h_1 a_1,$

 $\Delta_{\bullet} = h_{\bullet} f'_{\bullet}(x_1 x_2 x_3) + h_{\bullet} \alpha_{\bullet}$

 $\Delta_{\tau} = h_0 f'_{\tau}(z_1 z_2 x_0) + h_0 r_0.$ and for h=0,

 $\lim a_1 = 0, \quad \lim a_2 = 0 \quad \lim a_4 = 0$ Thus $\Delta f = df + \alpha_1 h_1 + \alpha_2 h_2 + \alpha_3 h_4$

Since the as converge to 0 f is totally differentiable at the point x

2 As a corollary of I, we have

Let $f(x_1, x_n)$ satisfy the conditions a) β) for a region R

f to totally differentiable at every point of R

the region R Then the difference quotient

427 1 Let the partial derivative fr. (z.

 $\frac{\Delta f}{\Delta z} = \frac{\partial f}{\partial z}$ uniformly

in any limited perfect domain D, in R

For, by the Law of the Mean,

$$\frac{\Delta f}{\Delta x_{\kappa}} = f'_{x_{\kappa}}(x_1 \cdots x_{\kappa} + \theta \Delta x_{\kappa} \cdots x_m).$$

But $f'_{x_{\kappa}}$, being continuous in D, the function on the right converges uniformly to $f_{x_{\kappa}}$, by 352.

2. Let the partial derivatives of the first order

$$f'_{x_1}, f'_{x_2}, \cdots f'_{x_m}$$

be continuous in the region R. Then the a's in

$$\Delta f = df + \alpha_1 \Delta x_1 + \dots + \alpha_m \Delta x_m$$

converge uniformly to 0, in any limited perfect domain D, in R.

For, referring to the proof of 426, we have

$$f'_{x_s}(x_1 \cdots x_{s-1}, x_s + \theta_s \Delta x_s, \overline{x}_{s+1} \cdots \overline{x}_m) = f'_{x_s}(x_1 \cdots x_m) + \alpha_s.$$

Hence by 1, the a's are uniformly evanescent.

428. 1. Let the first partial derivatives of $f(x_1 \cdots x_m)$ be continuous in the region R. Then f is continuous in R.

We have to show that

$$\lim_{h=0} f(x_1 + h_1 \cdots x_m + h_m) = f(x_1 \cdots x_m);$$

or, what is the same,

$$\lim_{\Delta = 0} \Delta f = 0. \tag{1}$$

But, by 426, 2, f is totally differentiable in R; hence

$$\Delta f = \partial f + \alpha_1 h_1 + \dots + \alpha_m h_m. \tag{2}$$

As

$$\lim_{\lambda=0} df = 0, \qquad \lim_{\lambda=0} \alpha_1 = 0, \qquad \cdots \lim_{\lambda=0} \alpha_m = 0;$$

passing to the limit in 2), we get 1).

2. As corollary, we have:

If all the partial derivatives of $f(x_1 \cdots x_m)$ of order n are continuous in the region R, then f, and all its partial derivatives of order < n, are also continuous in R.

429 1 At each point of a region R let

$$\Delta f = q_1 \Delta x_1 + q_m \Delta x_m + \alpha_1 \Delta x_1 + \alpha_m \Delta x_m, \qquad (1)$$

where the qs are functions of x and the as are functions of x and Δx . Let

$$\lim_{n \to \infty} \kappa_n = 0 \qquad \kappa = 1 \quad 2 \quad m \tag{2}$$

Then f is totally differentiable in R and

$$q_{s} = \frac{\partial f}{\partial x_{s}} \tag{3}$$

(4

For, let all the Δx s be 0 except Δx_s Then

$$\frac{\Delta f}{\Delta x_e} - q + a_e$$

Passing to the limit, we get 3) That f is totally differentiable follows now from 1) 2)

2 Let in R Then

$$df = \phi_1 dz_1 + + \phi_n dz_n$$

 $\phi_{\kappa} = \frac{\partial f}{\partial x_{\kappa}} \qquad \kappa = 1 \quad 2 \quad m$

For, by definition $df = \frac{\partial f}{\partial x_1} dx_1 + \frac{\partial f}{\partial x_2} dx_m$

Let all the dx_B , except dx_a be 0. Then

act and that the age, except the cost a section

$$df = \phi_s dx_s - \frac{\partial f}{\partial x_s} dx_s,$$

or

$$\left(\phi_{s} - \frac{\partial f}{\partial x_{s}}\right) dx_{s} = 0$$

As $dx \neq 0$ we have 4)

430 1 Let $f = f(u_1 \ u_n)$ and $u - g(x_1 \ x_m)$ is $= 1 \ 2$, n Let the image of the region X be the region U Let f be totally differentiable in U and each g be totally differentiable in X. Thus f variatived as a function of the xx is totally differentiable in X.

Since the g's are totally differentiable,

$$\Delta u_{i} = \sum_{\kappa'} \frac{\partial u_{i}}{\partial x_{\kappa}} \Delta x_{\kappa} + \sum_{\kappa} \alpha_{i\kappa} \Delta x_{\kappa}. \qquad i = 1, 2, \dots n. \\ \kappa = 1, 2, \dots m.$$
 (1)

Since $f(u_1 \cdots u_n)$ is totally differentiable,

$$\Delta f = \sum_{i} \frac{\partial f}{\partial u_{i}} \Delta u_{i} + \sum_{i} \beta_{i} \Delta u_{i}. \qquad i = 1, 2, \dots n.$$
 (2)

Replacing the values of Δu_i , given by 1), in 2), we get

where

$$\lim \gamma_1 = 0, \cdots \lim \gamma_m = 0, \tag{4}$$

when

$$\Delta x_1, \cdots \Delta x_m \doteq 0.$$

Then, by 429, 1), f, considered as a function of the x's, is totally differentiable; and

Also,

$$df = \sum_{i} \frac{\partial f}{\partial x_{i}} dx_{i} = \sum_{i} dx_{i} \sum_{\kappa} \frac{\partial f}{\partial u_{\kappa}} \frac{\partial u_{\kappa}}{\partial x_{i}} = \sum_{i,k} \frac{\partial f}{\partial u_{\kappa}} \frac{\partial u_{\kappa}}{\partial x_{i}} dx_{i}.$$
 (6)

2 We have f being considered as a function of the x s,

$$df = \sum_{s} dx \sum_{s} \frac{\partial f}{\partial u_{s}} \frac{\partial u_{s}}{\partial x} = \sum_{s} \frac{\partial f}{\partial u_{s}} \sum_{s} \frac{\partial u_{s}}{\partial x_{s}} dx_{s},$$

or

$$df = \sum_{i} \frac{\partial f}{\partial u_i} du_i$$

Thus to find df f considered as a function of the x s we may first find of considered as a function of the us and in the result replace the dus by their values in the x s

3 As a corollary of 1 we have

Let

be continuous in X Then f considered as a function of the xs is totally differentiable in X

For by 426 2 f considered as a function of the ue and the ue considered as functions of the xe are all totally differentiable Hence by 1 f considered as a function of the ze is totally differentiable

Some Properties of Differentials Higher Differentials

431 In this section we shall suppose the total differentials which occur exist in a certain region R in which $x = (x_1 x_m)$ ranges

1 Let
$$F = c_1 f_1 + c_2 f_n$$
 of a constants

Then $dF = c_1 f f_1 + c_2 f_n$
 $dF = \sum_{i=0}^{n} f_i dx$
 $dF = \sum_{i=0}^{n} dx = \sum_i c_i \frac{\partial f_i}{\partial x} dx$

$$= \sum_{s} c_{s} \sum_{s} \frac{\partial f_{s}}{\partial x} dx = \sum_{s} c_{s} df_{s}$$

2. Let
$$F = fg.$$

$$Then$$

$$dF = fdg + gdf.$$
For,
$$dF = \sum \frac{\partial (fg)}{\partial x_{\iota}} dx_{\iota} = \sum_{i} f \frac{\partial g}{\partial x_{\iota}} dx_{\iota} + \sum_{i} g \frac{\partial f}{\partial x_{\iota}} dx_{\iota}$$

$$= f \sum_{i} \frac{\partial g}{\partial x_{\iota}} dx_{\iota} + g \sum_{i} \frac{\partial f}{\partial x_{\iota}} dx_{\iota} = fdg + gdf.$$
3. Let
$$F = \frac{f}{g}. \qquad g \neq 0 \text{ in } R.$$
Then
$$dF = \frac{gdf - fdg}{g^{2}}.$$
For,
$$dF = \sum_{i} \frac{\partial F}{\partial x_{\iota}} dx_{\iota} = \sum_{i} \frac{g \frac{\partial f}{\partial x_{\iota}} - f \frac{\partial g}{\partial x_{\iota}}}{g^{2}} dx_{\iota}$$

$$= \frac{1}{g} \sum_{i} \frac{\partial f}{\partial x_{\iota}} dx_{\iota} - \frac{f}{g^{2}} \sum_{i} \frac{\partial g}{\partial x_{\iota}} dx_{\iota}$$

$$= \frac{df}{g} - \frac{fdg}{g^{2}} = \frac{gdf - fdg}{g^{2}}.$$

432. The partial derivatives involved, being supposed continuous in a certain region R, let us form the expressions

$$\begin{split} d^2f &= \sum_{\iota,\iota,\kappa} \frac{\partial^2 f}{\partial x_\iota \partial x_\kappa} dx_\iota dx_\kappa, \qquad \iota, \, \kappa = 1, \, 2, \cdots m. \\ \\ d^3f &= \sum_{\iota,\iota,\kappa} \frac{\partial^3 f}{\partial x_\iota \partial x_\jmath \partial x_\kappa} dx_\iota dx_\jmath dx_\kappa, \qquad \iota, \, \jmath, \, \kappa = 1, \, 2, \cdots m. \end{split}$$

They are called the second, third, \cdots differentials of $f(x_1 \cdots x_m)$, respectively, in R.

We notice:

$$dy' = \sum_{i} dx_i \sum_{\overline{a}z_i} \frac{\partial f'}{\partial z_i} dx_i$$

 $= \sum_{i} dx_i \sum_{\overline{a}} \frac{\partial f}{\partial z_i} (\frac{\partial f}{\partial z_i}) dx_i$
 $= \sum_{i} dx_i \ d(\frac{\partial f}{\partial z_i})$
 $= d\sum_{\overline{a}z_i} dx_i,$ (1)

since dz, acts as a constant with respect to the symbol d.

Then 1) gives

$$d^3f = d df$$

In the same way we find

$$d^{n}f = d d^{n-1}f = d^{n} d^{n-1}f$$

433 1 Let $w = f(u_i \quad u_*)$, while $u_1 \quad u_*$ are functions of $x_1 \quad x_n \quad \text{Let } w$ when considered as a function of the x_s , be denoted by $F(x_1 \quad x_m)$ Let finally all derivatives involved be continuous. Then

$$\begin{aligned}
dF &= \sum_{i} \frac{\partial f}{\partial u} du & (1) \\
d^{2}F &= \sum_{i} du d \frac{\partial f}{\partial u} + \sum_{i} \frac{\partial f}{\partial u_{i}} d^{2}u_{i} \\
&= \sum_{i} du \sum_{i} \frac{\partial^{2} f}{\partial u} du_{i} + \sum_{i} \frac{\partial^{2} f}{\partial u} d^{2}u_{i}
\end{aligned}$$

$$= d^{2}f + \sum_{i} \frac{\partial f}{\partial u} d^{2}u_{i} \qquad (2)$$

$$d^{3}F = \sum_{i\kappa} du_{i} du_{\kappa} d \cdot \frac{\partial^{2}f}{\partial u_{i} \partial u_{\kappa}} + \sum_{i\kappa} \frac{\partial^{2}f}{\partial u_{i} \partial u_{\kappa}} du_{i} d^{2}u_{\kappa}$$

$$+ \sum_{i\kappa} \frac{\partial^{2}f}{\partial u_{i} \partial u_{\kappa}} du_{\kappa} d^{2}u_{i} + \sum_{i} d^{2}u_{i} d \cdot \frac{\partial f}{\partial u_{i}}$$

$$+ \sum_{i} \frac{\partial f}{\partial u_{i}} d^{3}u_{i}$$

$$= \sum_{i\kappa\lambda} \frac{\partial^{3}f}{\partial u_{i} \partial u_{\kappa} \partial u_{\lambda}} du_{i} du_{\kappa} du_{\lambda} + 3 \sum_{i,\kappa} \frac{\partial^{2}f}{\partial u_{i} \partial u_{\kappa}} d^{2}u_{i} du_{\kappa} + \sum_{i} \frac{\partial f}{\partial u_{i}} d^{3}u_{i}$$

$$= d^{3}f + 3 \sum_{i} \frac{\partial^{2}f}{\partial u_{i} \partial u_{\kappa}} d^{2}u_{i} du_{\kappa} + \sum_{i} \frac{\partial f}{\partial u_{i}} d^{3}u_{i}.$$

$$(3)$$

In the same way the higher differentials d^4F ... can be calculated.

2. In case
$$d^2u_i = 0, \ d^3u_i = 0, \cdots$$
 we have $dF = df, \ d^2F = d^2f, \ d^3F = d^3f, \cdots$

434. Let all the partial derivatives of $f(x_1 \cdots x_m)$ of order n be continuous in the domain D of the point x.

Then, if x + h lies in D,

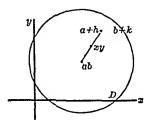

$$f(x_1 + h_1 \cdots x_m + h_m) = f(x_1 \cdots x_m) \quad \frac{1}{1!} df(x_1 \cdots x_m) + \frac{1}{2!} d^2 f(x_1 \cdots x_m) + \cdots + \frac{1}{n!} d^n f(x_1 + \theta h_1 \cdots x_m + \theta h_m); \tag{1}$$

setting $dx_{i} = h_{i}$, and $0 < \theta < 1$.

The expression on the right of 1) is called Taylor's development of f in finite form.

For simplicity we shall suppose m=2. The reasoning in the general case is precisely the same.

To avoid writing indices, we shall call the variables x, y.

Let x, y be any point on the line L joining the points a, b and a+h, b+k Then

$$x=a+uh$$
, $y=b+uk$ $0 \le u < 1$.

Also let

$$f(x,y) = f(a+uh, b+uk) = g(u)$$

Then, when u runs over the reterval $\mathfrak{A} = (0, 1)$, the point xy runs over the interval on L between a, b and a + b, b + k. By 433, 1, we have

$$g'(u) = \frac{\partial f}{\partial x}h + \frac{\partial f}{\partial y}k = df(x, y),$$

$$g''(u) = d^2f(x, y), \qquad g'''(u) = d^*f(x, y).$$

Thus g(u) and its first n derivatives are continuous functions of u in \mathfrak{I}

Applying 409, we have

$$g(u) = g(0) + \frac{u}{1!}g'(0) + \frac{u^2}{2!}g''(0) + \frac{u^*}{n!}g^{(n)}(\theta u)$$

0 < \theta < 1.

Setting here u = 1, and observing that

$$g(1) = f(a+h, b+k), g(0) = f(a, b),$$

$$g'(0) = df(a, b), g''(0) = d^2f(a, b), \cdots$$

 $g^{(a)}(\theta u) = d^a f(a + \theta h, b + \theta k),$ we get

$$f(a+b,b+k) = f(a,b) + \frac{1}{1!} df(a,b) + \frac{1}{2!} d^2f(a,b) + \dots$$
$$+ \frac{1}{a!} \frac{1}{1!} d^{a} f(a,b) + \frac{1}{a!} d^2f(a+b,b+bk)$$

435 In Taylor's development of a function f(x) of a single variable [409], we have only assumed that $f^{(n)}(x)$ is finite within \mathfrak{A} , whereas, in the corresponding development of a function of

several variables, we have assumed [434] that all the partial derivatives of order n are continuous in D(a), in order to use 430.

It is interesting to note that the development may not hold if these derivatives are not continuous.

Consider the function

$$f(xy) = \sqrt{|xy|},$$

employed in 424, 1.

· We have

$$f'_x = \frac{1}{2} \frac{xy^2}{\sqrt{|xy|^3}}, \quad f'_y = \frac{1}{2} \frac{x^2y}{\sqrt{|xy|^3}}; \qquad x, y \neq 0.$$

$$f'_x(x, 0) = 0, f'_y(0, y) = 0.$$

The derivatives of the first order are thus continuous, except at the origin.

Let P = (x, x), Q = (x + h, x + h) be two points on the line y = x, which we call L.

If now Taylor's development were true in a domain about a, in which the nth partial derivatives were finite, we could write, taking here n = 1,

$$f(x+h, x+h) = f(x, x) + h\{f'_x(\xi, \xi) + f'_y(\xi, \xi)\},$$
 (1)

where (ξ, ξ) is a point on L between P, Q.

This formula should be valid for all x, h. But in the present case

$$f'_x(\xi, \xi) = f'_y(\xi, \xi) = \frac{1}{9} \operatorname{sgn} \xi.$$

Thus 1) gives

$$|x+h| = |x| + h \operatorname{sgn} \xi.$$

That this result is false is easily seen.

For example, let

$$x = -1, h = 5.$$

Then 2) gives

$$4=1\pm 5$$
, if $\xi \neq 0$

$$=1, \qquad \text{if } \xi=0.$$

CHAPTER IX

IMPLICIT FUNCTIONS

436 1 Let $F(x_1 \quad x_n, u) = 0$

be a relation between the m+1 variables $x_1 \cdot x_m \cdot u$ Let

$$x_1 = a_1, \quad x_n = a_n$$

be a set of values such that the equation

 $F(a_1 \quad a_n, u) = 0$

is satisfied for at least one value of u. ie the equation 2) in u admits at least one root Let D be the aggregate of the points $x = (x, x_n)$ for which 1) has at least one root u We may con aider u as a function of the xs, $u = \phi(x, x_n)$ defined over D, where $\phi(x, x_n)$ has assigned to it at the point x, the roots u of 1) at this point

We say u is the implicit function defined by 1) It is in general a many valued function

EXAMPLES

1. Let

73 y = f(z)

 α

(2

be defined over a domain D Let E be the image of D Then 3) defines an inverse function x = q(x)

defined over E, by 217 This same function may be considered as an implicit function, defined by y - f(x) - F(x, y) - 0

2. Let f(x) = 1 for every x in D = (01) If we set v = f(x)

the image E of D is the single point y-1. The inverse function x = g(y)

is defined only for y = 1, at this point g takes on all values between 0 and 1 282

3. Let F = 0 be the relation

$$x^2 + y^2 + z^2 - r^2 = 0, \quad r \neq 0.$$
 (4)

At each point of the domain D,

$$x^2+y^2 = r^2$$

the equation 4) admits one, and in general, two values of z. The equation 4) therefore defines z as a two-valued implicit function u of x, y, over the domain D.

4.
$$x^2 + y^2 + z^2 = 0.$$
 (5)

In this case there is only one set of values, viz. x = y = z = 0 satisfying 5). Thus z is defined only for a single point, viz. x = y = 0. At this point, z = 0.

5.
$$x^2 + y^2 + z^2 + r^2 = 0. \qquad r \neq 0. \tag{6}$$

This equation is satisfied for no set of values of x, y, z. The equation 6), therefore, does not define any function z of x, y.

6.
$$\sin^2 u + \cos^2 u - \frac{x}{y} = 0.$$
 (7)

This equation admits no solution except for points on the line

$$y=x$$
.

For all points on this line, the origin excepted, the equation 7) is satisfied for any value of u in \Re .

2. More generally, let

$$F_1(x_1 \cdots x_m, u_1 \cdots u_p) = 0$$

$$\vdots \qquad \vdots \qquad \vdots$$

$$F_p(x_1 \cdots x_m, u_1 \cdots u_p) = 0$$
(S

be a system of p relations between the m+p variables x, u. Let D be the aggregate of points $x=(x_1\cdots x_m)$, for which the system S is satisfied for at least one set of values of $u_1\cdots u_p$. We may consider the u's as functions of the x's.

$$u_1 = \phi_1(x_1 \cdots x_m)$$

$$\vdots$$

$$u_p = \phi_p(x_1 \cdots x_m),$$

where the ϕ 's have assigned to them at the point x, the values of the roots $u_1 \cdots u_p$ at this point. We say $u_1 \cdots u_p$ is a system of implicit functions defined by the system S. These functions are, in general, many valued.

3 Suppose we know that a set of values

$$x_1 = a_1$$
 $x_m = a_m$ $u_1 = b_1$ $u_j = b_p$

satisfies the system S Let us call the set of values $u_1 = b_1$ $u_2 = b_3$

matral nature We wish to show now that under certain conditions, the system

S defines over a region R a set of p one valued continuous func tions u, u, in the variables z, x, satisfying S for every point of R, and taking on the above initial values at the point x=aFurthermore there is only one such system of functions

The method employed is due to Goursat Bull Soc Math de France, vol. 31 (1903) p. 184. It rests on a principle having many applications in analysis, known as the Method of Successive Approximation

437 1 Let us first consider only two variables. The method employed for this simple case is readily extended to the most gen eral case. We begin by establishing the fundamental

Lemma Let f(x, u) be continuous and df exist in the domain D, defined by

$$\mathfrak{A}$$
, $|x-a| \leq \sigma$,

94. 14-BI<T Let f vanish at a, b Let \theta be an arbitrary positive number < 1.

such that
$$\left|\frac{\partial f}{\partial x}\right| < \theta$$
 in D , (1

 $|f(x \ b)| < \tau(1-\theta) = \eta < \tau \text{ in } \mathbb{I}$ (2 Then

u - b = f(x, u)(3

admits one and only one solution

enhela

$$U = \phi(x)$$
, in \mathfrak{A}

which is continuous at a and takes on the initial value u = b at x = a.

The function ϕ is continuous in A, and remains in B while x runs over A.

We set

$$u_1 - b = f(x, b), u_2 - b = f(x, u_1), u_3 - b = f(x, u_2), \dots$$

Then all these u's fall in B.

For, by 2), u_1 falls in \mathfrak{B} . Let us admit that u_{r-1} falls in \mathfrak{B} , and show that u_r also falls in \mathfrak{B} .

In fact, by the Law of the Mean,

$$u_{r} - u_{1} = (u_{r} - b) - (u_{1} - b)$$

$$= f(x, u_{r-1}) - f(x, b)$$

$$= (u_{r-1} - b) \frac{\partial f(x, u')}{\partial u}$$
(4)

Hence, by 1),

$$|u_r - u_1| < \theta |u_{r-1} - b| \tag{5}$$

$$<\theta\tau$$
, (6)

since, by hypothesis, u_{r-1} falls in \mathfrak{B} .

Thus, from $u_r - b = (u_r - u_1) + (u_1 - b)$ and 6), we have

 $|u_r-b|<|u_1-b|+\theta\tau$.

But

$$|u_1 - b| = |f(x, b)| < (1 - \theta)\tau$$
, by 2).

Hence,

$$|u_r - b| < \tau; \tag{7}$$

i.e. all the u's fall in B.

We show now that for each x in \mathfrak{A} ,

$$U = \lim u_n = \phi(x)$$

is finite. To this end we show

$$\epsilon > 0, \quad m, \quad |u_n - u_m| < \epsilon, \quad n > m.$$
 (8)

For, in the same way that we established 5), we can show that

$$|u_r - u_{r-1}| < \theta |u_{r-1} - u_{r-2}|. \tag{9}$$

Thus, we get

$$|u_2 - u_1| < \theta |u_1 - b| |< \theta \eta,$$

 $|u_4 - u_4| < \theta |u_4 - u_4| < \theta^2 \eta,$ (10)

$$|u_1-u_2|<\theta|u_1-u_2|<\theta^3\eta_1$$
 etc.

Hence

$$|u_4 - u_3| < \theta |u_3 - u_3| < \theta^{-\gamma}$$
, etc
 $|u_4 - u_3| < \eta \theta^{-\gamma} (1 + \theta + + \theta^{-\gamma - 1})$
 $< \frac{\eta \theta^{-\gamma}}{1 - \theta}$ since $0 < \theta < 1$
 $< \epsilon$.

if m is taken sufficiently large

Thus the relation 8) is established

Furthermore, the above reasoning shows that one and the same m suffices wherever x is taken in $\mathfrak A$ Thus u_n converges uniformly to U in $\mathfrak A$

Finally, by virtue of 7) U falls in B The function U satisfies 3) in M

The func

$$v_a - b = f(x, u_{a-1})$$

let $n = \infty$. Since f is continuous, we get in the limit

$$U - b = f(x, \overline{U})$$

We show now that $U = \phi(x)$ is continuous in $\mathfrak A$ for, since u_x converges uniformly to $\phi(x)$ in $\mathfrak A$, we have

$$\phi(x+h) = u_n(x+h) + \epsilon', \quad |\epsilon'| < \frac{\epsilon}{3}$$

$$\phi(x) = u_n(x) + \epsilon^{H_n} \qquad \left[\epsilon^{H}\right] < \frac{\epsilon}{3}$$

 $\varphi(x) = u_n(x) + e^{-x}$ If n is taken large enough

But u_1, u_2 , are continuous functions of x, since f is continuous Thus, for sufficiently small δ_i

$$|u_s(x+\hbar)-u_s(x)|<\frac{\epsilon}{2}$$

for |h| < 8 and x + h m M

Hence

$$|\phi(x+h)-\phi(x)|<\epsilon.$$

We show now that U is the only root of 3) which is continuous at a and takes on the initial value b at a.

For, let $V = \psi(x)$ be such a solution.

If x is taken sufficiently near a, V falls in \mathfrak{B} .

Then from

$$V-b=f(x, V),$$

$$u_n - b = f(x, u_{n-1}),$$

we have, by the Law of the Mean,

$$\begin{aligned} |V - u_n| &= |f(x, V) - f(x, u_{n-1})| \\ &= |V - u_{n-1}| \left| \frac{\partial f(x, u')}{\partial u} \right| \\ &< \theta |V - u_{n-1}|, \quad \text{by 1}), \\ &< \theta^{n-1} |V - u_1|. \end{aligned}$$

Hence, passing to the limit, $n = \infty$,

$$V-U=0$$
, for all points of \mathfrak{A} .

2. As corollary of 1, we have:

Let

$$f(x, u), \frac{\partial f}{\partial u}$$

be continuous in the domain of the point (a, b), and vanish at that point.

Then

$$u-b=f(x,u)$$

admits a unique solution

$$u = \phi(x)$$
,

which is continuous in the domain of x=a, and has the initial value u=b at x=a.

438 1. By means of the preceding lemma, we can now prove the theorem.

Let F(x,u) be continuous, and F exist in the domain D, defined by

$$\mathfrak{A}$$
, $|x-a| \leq \sigma$

$$u-\delta \leq r$$

At a, b let F = 0, while $F'_u \neq 0$

Let 0 be an arbitrary positive number < 1, such that

$$\left|1 - \frac{F_*(x \ u)}{F_*'(a, \ b)}\right| < \theta, \quad \text{in } D,$$

while

$$\left|\frac{F(x-b)}{F'_1(a,b)}\right| < (1-\theta)\tau, \quad \text{in it.}$$
 (2)

Then the equation

$$F(x, u) = 0 (3$$

se eatisfied by a one valued continuous Junction

$$u = \phi(x), \quad \text{in } \mathfrak{A},$$

having the initial value b at x = a, and which remains in B while x is in A.

Furthermore, 3) admits no other solution which is continuous at 4,

Furthermore, 3) admits no other solution which is continuous at a and has the initial value b at a

For, consider the equation

$$u - b = u - b - \frac{F(x, u)}{F'_{u}(a, b)} = f(x, u)$$
 (4)

Evidently this is equivalent to 3), i.e every function u which satisfies 3) satisfies 4), and conversely.

Here

$$\frac{\partial f}{\partial u} = 1 - \frac{F_{\bullet}'(x, u)}{F_{\bullet}'(a, b)}$$

Hence f is continuous, and f_{-}^{c} exists in D, also f vanishes at a, b.

Furthermore, from 1)

$$\left|\frac{\partial f}{\partial u}\right| < \theta$$
, in D .

while from 2),

$$|f(x, b)| < (1 - \theta)\tau$$
, in \mathfrak{A}

Thus f and f'_u satisfy all the conditions of the lemma in 437, and the theorem follows at once.

2. The reader should remark that the preceding theorem makes no assumption regarding F'_x . This may not even exist.

For example, let

$$x\sin\frac{1}{x}=0$$
, for $x=0$.

Consider

$$F(x, u) = u^3 - x \sin \frac{1}{x} = 0. ag{5}$$

Here F'_x does not exist at x=0, u=0. However, the equation 5) defines a continuous one-valued function, which takes on the initial value u=0 for x=0; viz.,

$$u = \sqrt[3]{x \sin \frac{1}{x}}.$$

3. As corollary of 1 we have:

In the domain of the point a, b, let

$$F(x, u), F'_u(x, u)$$

be continuous. At the point a, b, let

$$F=0, F'_{\mu}\neq 0.$$

Then the equation F(x, u) = 0 admits a unique solution

$$u = \phi(x)$$
,

which is continuous in the domain of the point x = a, and has the initial value u = b, at this point.

439 We have seen in 438 that

$$F(x,u)=0 (1$$

is satisfied by a continuous function

$$u = \phi_1(x)$$

in a certain interval $(a-\sigma, a+\sigma)=(A B)$ and that there is only one such function which = δ when x = a In general this is true not only for the interval (A B) determined by the theorem 438 but for a larger interval (C, D), containing (A, B) For let a. be a point near one of the end points of (A B) Let b = d.(a.) Let us replace a b in the theorem of 438 by a, b, Then the con ditions of this theorem are satisfied for a certain interval (A. B.). about at, to which corresponds a continuous function

$$u = \phi_3(x)$$
,

determined by the condition that u = b, for x = a. The interval (A, B,) will in general extend beyond (A B) In the interval (A. B) which the two intervals (A B) (A, B,) have in common. the two functions

$$\phi_1(u)$$
 $\phi_3(u)$

are equal. Let us define a function

$$u = \phi(x) = \phi_1(x)$$
 in $(A B)$,

$$= \phi_2(x) \quad \text{in } (A_1 \ B_1)$$

Then the equation 1) is satisfied by this function in (A, B_1) , and it is uniquely determined by the

fact that it is continuous in (A B.) and has the value u = b for x = aIn this way we can continue extend ing on the right, and on the left, the original interval, until we are blocked by certain points beyond which we cannot go Such points may arise when F(x | u) ceases to be continuous, or when F' = 0

440. 1. We proceed now to extend the theorem of 438 to embrace the system S of 436.

To this end we generalize the lemma of 437 as follows:

Lemma. Let

$$f_1(x_1 \cdots x_m u_1 \cdots u_p) \cdots f_p(x_1 \cdots x_m u_1 \cdots u_p),$$

$$\frac{\partial f_i}{\partial u_r} \qquad \iota, \ \kappa = 1, \ 2, \ \cdots \ p.$$

be continuous in the domain D defined by

$$\begin{aligned} \mathfrak{A}; & |x_1 - a_1| \leq \sigma \cdots |x_m - a_m| \leq \sigma, \\ \mathfrak{B}; & |u_1 - b_1| < \tau \cdots |u_n - b_n| < \tau, \end{aligned}$$

and let $f_1, \dots f_p$ vanish at the point $(a_1 \dots a_m b_1 \dots b_p)$. Let θ be an arbitrary positive number < 1, such that

$$\left|\frac{\partial f_{\iota}}{\partial u_{\epsilon}}\right| < \frac{\theta}{p}, \quad \iota, \ \kappa = 1, \ 2, \ \cdots \ p, \quad in \ D.$$
 (1)

while

and

$$|f_{\iota}(x_1\cdots x_mb_1\cdots b_p)| < \tau(1-\theta) = \eta, \quad \text{in } \mathfrak{A}. \qquad \iota = 1, 2, \cdots p. \quad (2)$$

Then the equations

$$u_1 - b_1 = f_1(x_1 \cdots u_p) \quad \cdots \quad u_p - b_p = f_p(x_1 \cdots u_p)$$

admit one, and only one, set of solutions

$$U_1 = \phi_1(x_1 \cdots x_m) \quad \cdots \quad U_p = \phi_p(x_1 \cdots x_m)$$

in \mathfrak{A} , which are continuous at a, and take on the initial values $b_1 \cdots b_p$, at x = a.

The functions ϕ are continuous in \mathfrak{A} , and remain in \mathfrak{B} , as x runs over \mathfrak{A} .

We set

$$u_{11} - b_1 = f_1(x_1 \cdots x_m b_1 \cdots b_p)$$

$$\vdots \qquad \vdots \qquad \vdots$$

$$u_{p1} - b_p = f_p(x_1 \cdots x_m b_1 \cdots b_p)$$

$$u_{12} - b_1 = f_1(x_1 \cdots x_m u_{11} \cdots u_{p1})$$

$$\vdots \qquad \vdots$$

$$u_{p3} - b_p = f_p(x_1 \cdots x_m u_{11} \cdots u_{p1})$$
eto.

We show now that all these us he in &

For, by 2), u_{11} u_{p1} are in \mathfrak{B} Let us assume now that u_{1r-1} $u_{p,r-1}$ lie in \mathfrak{B} , and show that u_{1r} u_{pr} also lie in \mathfrak{B} By the Law of the Mean.

$$u_r - u_1 = (u_1, v_1 - b_1) \frac{\partial f_1}{\partial u_1} + (u_{p,r}, v_1 - b_p) \frac{\partial f_1}{\partial v_1}$$

the arguments of these derivatives lying in D Hence, by 1),

$$|u_{r} - u_{rl}| < \frac{\theta}{p} \{|u_{\lambda_{r-1}} - b_{l}| + + |u_{p-r-1} - b_{g}|\}$$
 (3)

<θτ

Thus, as
$$u_{ir} - b_i = (u_{ir} - u_1) + (u_{il} - b_i)_i$$

we have

$$|u_{\tau} - b_{\epsilon}| < |u_{1} - b_{\epsilon}| + \theta \tau, \quad \epsilon = 1, 2, \quad p$$

or using 2),

$$|u_{p}-\delta_{i}|<\tau, \quad i=1,2, \quad p, \ r=2,3,$$

which was to be shown

We show now that for each z in II,

$$U_i = \lim_{n \to \infty} u_{n,n} = \phi_i(x_1 - x_n)$$

18 finite

To this end we show that

$$\epsilon > 0$$
, m , $|u_{in} - u_{im}| < \epsilon$ $n > m$ (4)

i=1, 2, p

$$|u_{x}-u_{x+1}| < \frac{\theta}{p}\{|u_{1+1}-u_{1+2}| + |u_{p+1}-u_{p+2}|\}$$
 (5)

Then

$$|u_3 - u_{41}| < \theta_{\eta}$$
 by 2) and 3),

$$|u_{i2} - u_{i,2}| < \theta^2 \eta$$
, by 5),

$$|v_{n,n}-v_{n,n}|<\theta^{n}$$
, etc.

These relations are analogous to the relations 10) in 437. The rest of the demonstration can now be conducted as in 437 to establish

lish not only the relation 4), but the remainder of the theorem in hand.

2. We can state 1 in a form less explicit, but easier to remember, as follows:

Let

and

$$f_1(x_1\cdots x_m, u_1\cdots u_p) \quad \cdots \quad f_p(x_1\cdots x_m, u_1\cdots u_p),$$

$$\frac{\partial f_{\epsilon}}{\partial u_{\epsilon}} \qquad \iota, \, \kappa=1, \, 2, \, \cdots \, p.$$

be continuous in the domain of the point $a_1 \cdots a_m b_1 \cdots b_p$. Let these $p^2 + p$ functions vanish at this point.

Then the system of equations

$$u_1 - b_1 = f_1(x_1 \cdots u_p)$$
 ... $u_p - b_p = f_p(x_1 \cdots u_p)$

admits a unique system of solutions

$$u_1 = \phi_1(x_1 \cdots x_m) \quad \cdots \quad u_p = \phi_p(x_1 \cdots x_m),$$

which is continuous in the domain of the point $x_1 = a_1 \cdots x_m = a_m$, and takes on the initial set of values $u_1 = b_1 \cdots u_p = b_p$.

441. We can now generalize 438 as follows:

Let

and

$$F_1(x_1 \cdots x_m u_1 \cdots u_p) \quad \cdots \quad F_p(x_1 \cdots x_m u_1 \cdots u_p),$$

$$\frac{\partial F_i}{\partial u} \qquad \iota, \ \kappa = 1, \ 2, \ \cdots \ p. \tag{1}$$

be continuous in the domain D of the point

$$Q; x_1 = a_1 \cdots x_m = a_m, \ u_1 = b_1 \cdots u_p = b_p.$$

Let $F_1 \cdots F_p$ vanish at Q, while the derivatives 1) have the values

 $d_{..}$ at Q.

Let

$$\Delta = \begin{vmatrix} d_{11} \cdots d_{1p} \\ \vdots & \ddots & \vdots \\ d_{p_1} \cdots d_{p_p} \end{vmatrix} \neq 0.$$

Then the system of equations

$$F_1=0$$
 $F_2=0$ (8

is satisfied by a set of functions

$$u_1 = \phi_1(x_1 \quad x_n)$$

$$u_p = \phi_p(x_1 \quad x_n),$$

which are one valued and continuous in a certain region A, about the point

$$a$$
, $x_1 = a_1$ $x_n = a_{n1}$

and at this point, these functions have the values

$$u_1 = b_1$$
 $u_p = b_p$

Furthermore, the system S admits no other set of p functions, continuous at a and taking on the initial values b at that point

We replace the system S by the equivalent system

$$\begin{split} d_{11}(u_1-b_1)+&+d_{1p}(u_p-b_p)=d_{11}(u_1-b_1)+\cdots\\ &+d_{1p}(u_p-b_p)-F_1=g_1\\ &\cdot&\cdot&\cdot\\ d_{p1}(u_1-b_1)+&+d_{pp}(u_p-b_p)=d_{p1}(u_1-b_1)+\cdots \end{split} \tag{2}$$

$$+ d_{pp}(u_p - b_p) - F_p = g_p.$$

Since $\Delta \neq 0$, we can solve this system for the differences $u_i - b_i$, and get $u_i - b_i = e_{1i}g_1 + \dots + e_{1r}g_r = f_1$

$$u_1 - b_1 - e_{11}y_1 + \cdots + e_{1p}y_p = f_1$$

$$\vdots$$

$$u_p - b_p = e_{p1}g_1 + \cdots + e_{pp}g_p = f_p$$
(

Obviously, the functions g, and hence the functions f, are continuous in D

So are the derivatives $\frac{\partial f}{\partial u_{\kappa}}$. For

$$\frac{\partial f_{\iota}}{\partial u_{\kappa}} = e_{\iota 1} \frac{\partial g_{1}}{\partial u_{\kappa}} + \dots + e_{\iota p} \frac{\partial g_{p}}{\partial u_{\kappa}}, \quad \iota, \kappa = 1, 2 \cdots p. \quad (4)$$

where

$$\frac{\partial g_r}{\partial u_{\kappa}} = d_{r\kappa} - \frac{\partial F_r}{\partial u_{\kappa}}.$$
 (5)

Since the g's vanish at Q, so do the f's. Since the derivatives 5) vanish at Q, so do also the derivatives 4).

Obviously, therefore, the numbers σ, τ, θ of lemma 440 exist, such

that

$$\left|\frac{\partial f_i}{\partial u_s}\right| < \frac{\theta}{p}, \quad \text{in } D.$$

$$|f(x_1 \cdots x_m b_1 \cdots b_n)| < \tau (1 - \theta),$$

We can therefore apply this lemma to the system 3). Since this stem and the given system S are equivalent the theorem is

system and the given system S are equivalent, the theorem is proved.

442. 1. Let
$$f(x_1 \cdots x_m, u) = 0$$
 (1)

admit a solution u=b, at the point x=a. In D(a,b), let $f(x_1\cdots x_m u)$ have continuous first partial derivatives. Let $f'_u \neq 0$ in D. Then 1) defines a one-valued function u, in a certain domain Δ , of the point a, whose first partial derivatives in Δ are given by

$$\frac{\partial u}{\partial x_{\iota}} = -\frac{f'_{x_{\iota}}}{f'_{u}}. \qquad \iota = 1, 2, \dots m.$$
 (2)

For, let x be a point of Δ . Let x receive the increment Δx_i , while the other coördinates of x remain constant. Let the corresponding increment of u be Δu . Then

$$f(x_1 \cdots x_i + \Delta x_i \cdots x_m u + \Delta u) - f(x_1 \cdots x_m u) = 0, \tag{3}$$

by virtue of 1). Applying the Law of the Mean to 3), we have, setting $x'_i = x_i + \theta \Delta x_i$, $u' = u + \theta \Delta u$,

$$f'_{x_i}(x_1\cdots x_i'\cdots x_mu')\Delta x_i + f'_{u}(x_1\cdots x_i'\cdots x_mu')\Delta u = 0;$$

whence

$$\frac{\Delta u}{\Delta z_i} = -\frac{f'_{z_i}(z_1 \quad z'_i \quad z_n u')}{f'_{z_i}(z_1 \quad z'_i \quad z_n u')}$$

Passing to the limit, we get 2)

$$2 df = \frac{\partial f}{\partial x_1} dx_1 + + \frac{\partial f}{\partial x_m} dx_m + \frac{\partial f}{\partial u} du = 0 \frac{\partial f}{\partial u} \neq 0 (4)$$

For, by 2),

$$du = -\frac{\frac{\partial f}{\partial x_1}}{\frac{\partial f}{\partial u}} dx_1 - -\frac{\frac{\partial f}{\partial x_n}}{\frac{\partial f}{\partial u}} dx_n.$$

Multiplying by the common denominator, we have 4).

443 1 Let the system

$$\Gamma_1(x_1 - x_m, u_1 - u_p) = 0$$

 $F_*(x_1 - x_m, u_1 - u_p) = 0$
(1)

admit a solution u = b at the point x = a Let the functions F_1 F_2 have continuous first partial derivatives in D(a, b). Let

$$J = \begin{vmatrix} \frac{\partial F_1}{\partial A_1} & \frac{\partial F_p}{\partial u_1} \\ \frac{\partial F_1}{\partial v} & \frac{\partial F_p}{\partial v} \end{vmatrix} \neq 0, \quad \text{in } D.$$

Then 1) defines a system u_1-u_s of one valued functions in a certain domain Δ of the point a, whose first partial derivatives $\frac{\partial J_s}{\partial x_a}$ in Δ are given by the system of equations

$$\frac{\partial F_1}{\partial x_x} + \frac{\partial F_1}{\partial u_1} \frac{\partial u_1}{\partial x_x} + \frac{\partial F_1}{\partial u_p} \frac{\partial u_p}{\partial x_x} = 0$$

$$(2)$$

$$\frac{\partial F_2}{\partial x_x} + \frac{\partial F_2}{\partial u_1} \frac{\partial u_1}{\partial x_x} + \frac{\partial F_2}{\partial u_1} \frac{\partial u_p}{\partial x_x} = 0,$$

with non vanishing determinant J.

For, let $P = (x_1 \cdots x_m u_1 \cdots u_p)$ be a point of D. Let $\Delta u_1 \cdots \Delta u_p$ be the increments of $u_1 \cdots u_p$, corresponding to an increment Δx_{κ} of x_{κ} . Let $0 < \theta_i < 1$, and

$$Q_{\iota} = (x_1 \cdots x_s + \theta_{\iota} \Delta x_s \cdots x_m, u_1 + \theta_{\iota} \Delta u_1 \cdots u_p + \theta_{\iota} \Delta u_p). \quad \iota = 1, 2, \cdots p.$$

Let ϕ_i be the value of $\frac{\partial F_i}{\partial x_{\kappa}}$, and ψ_{ir} be the value of $\frac{\partial F_i}{\partial u_r}$ at Q_i . Then, by the Law of the Mean, we have from 1),

$$\Delta F_1 = \phi_1 + \psi_{11} \frac{\Delta u_1}{\Delta x_{\kappa}} + \psi_{12} \frac{\Delta u_2}{\Delta x_{\kappa}} + \dots + \psi_{1p} \frac{\Delta u_p}{\Delta x_{\kappa}} = 0$$

$$\Delta F_p = \phi_p + \psi_{p1} \frac{\Delta u_1}{\Delta x_{\kappa}} + \psi_{p2} \frac{\Delta u_2}{\Delta x_{\kappa}} + \dots + \psi_{pp} \frac{\Delta u_p}{\Delta x_{\kappa}} = 0.$$
(3)

Thus,

$$\frac{\Delta u_1}{\Delta x_{\kappa}} = - \begin{vmatrix} \psi_{11} \cdots \phi_1 \cdots \psi_{1p} \\ \psi_{21} \cdots \phi_2 \cdots \psi_{2p} \\ \vdots & \vdots \\ \psi_{p_1} \cdots \phi_p \cdots \psi_{pp} \end{vmatrix} : \begin{vmatrix} \psi_{11} \cdots \psi_{1p} \\ \psi_{21} \cdots \psi_{2p} \\ \vdots \\ \psi_{p_1} \cdots \psi_{pp} \end{vmatrix}.$$

Let $\Delta x_s \doteq 0$; the limit of the right side exists, since the partial derivatives of the F's are continuous, and $J \neq 0$. Hence the derivatives $\frac{\partial u_s}{\partial x_s}$ exist. Hence in the limit, the system 3) goes over into the system 2).

2. The determinant J is called the Jacobian of the system 1).

CHAPTER X

INDETERMINATE FORMS

Application of Taylor's Development in Finite Form

444 The object of the present chapter is to show how in cer tain cases we may determine the limit of expressions of the type

$$\frac{f(z)}{g(z)} \ f(z) \ g(z) \ f(x) - g(x), \ f(z)^{g(z)}$$

which, on replacing f(z), g(z) by their limits, assume the forms $\frac{0}{c}$, $\frac{\omega}{\infty}$, 0, ∞ , $\infty - \infty$, 1^{∞} , 0° , ∞°

These are ordinarily called indeterminate forms

445 Suppose by the sid of Taylor's development in finite form, or otherwise, we find that, in R = RD(a),

f(x)=a(x-a)"+
$$\phi(x)$$
(x-a)", m'>m

$$g(x) = \beta(x-a)^n + \psi(x)(x-a)^n, \qquad n! >$$

where ϕ ψ are limited in R, and α , $\beta \neq 0$ Then

$$\frac{f(x)}{g(x)} = \frac{\alpha + (x-a)^n}{\beta + (x-a)^n} \stackrel{\text{wh}}{=} (x-a)^n \quad x \neq a$$

Passing to the limit x = a, we have

$$R \lim_{x \to \infty} \frac{f(x)}{g(x)} = \begin{cases} 0, & \text{if } m > n, \\ \alpha/\beta, & \text{if } m = n, \\ \sigma & \infty, & \text{if } m < n. \end{cases} \quad \sigma = \operatorname{sgn} \frac{\alpha}{\beta}.$$

Similar considerations apply to the left hand limit at a

For,
$$\lim_{x \to 0} \frac{e^x - e^{\sin x}}{x - \sin x} = +1.$$

$$e^x = 1 + \frac{x}{1!} + \frac{x^2}{2!} + \frac{x^3}{3!} + x^4 \phi_1(x).$$

$$e^{\sin x} = 1 + x + \frac{1}{2} x^2 + x^4 \phi_2(x).$$

$$f(x) = e^x - e^{\sin x} = \frac{1}{6} x^5 + x^4 \phi(x).$$
Similarly

Similarly,

$$g(x) = x - \sin x = \frac{1}{6}x^3 + x^5\psi(x).$$

The functions ϕ , ψ are limited in D(0).

Thus,

$$\frac{f(x)}{g(x)} = \frac{\frac{1}{6} + x\phi(x)}{\frac{1}{6} + x^2\psi(x)},$$

whose limit for z = 0 is 1.

To find the limit of 446.

$$\int f(x) - g(x), \tag{1}$$

when f and g are infinite in the limit, we may sometimes find a development of f(x), g(x) in the form

$$\frac{\alpha_{-m}}{(x-a)^{n_1}} + \frac{\alpha_{-m+1}}{(x-a)^{m-1}} + \dots + \alpha_0 + \alpha_1(x-a) + \dots + (x-a)^n \phi(x),$$

valid in D(a) or RD(a), the function ϕ being limited here.

This method of finding the limit of 1) is best illustrated by an example.

$$\lim_{x=0} \left(\frac{1}{x} - \csc x \right) = 0.$$

We have

cosec
$$x = \frac{1}{\sin x} = \frac{1}{x\{1 - x^2\phi(x)\}}, \quad \phi(x) \doteq \frac{1}{6}.$$

$$\frac{1}{1 - x^2 \phi(x)} = 1 + \frac{x^2 \phi(x)}{1 - x^2 \phi(x)} = 1 + x^2 \psi(x), \quad \psi(x) \doteq \frac{1}{6}.$$

Hence

$$\csc x = \frac{1}{x} \{1 + x^2 \psi(x)\}.$$

Therefore

$$\frac{1}{x} - \csc x = -x\psi(x) \doteq 0.$$

447 When the independent variable $x = +\infty$, we may set

$$z=\frac{1}{u}$$

which converts the limit into R lim, by 290.

Example $y = x(\sigma - 1), \quad \sigma > 0.$ $\lim_{y \to 1} y = \log a.$ For, $\sigma = \sigma^{\alpha} = \sigma^{\alpha} + 0 \Rightarrow 1 + u \log a + u^{\beta} \phi(a),$ where $\phi(u) = \frac{1}{2} \log^{\alpha} a.$

 $\gamma = \log a + *\phi(*)$

= log a.

448 When the preceding methods are not convenient, we may often apply with success one of the following theorems These rest on

Cauchy's theorem Let f(x), g(x) be continuous in $\mathfrak{A}=(a,b)$ Within \mathfrak{A} , let f'(z) be finite or infinite and g'(z) finite and ϕ 0. Then

$$\frac{f(b) - f(a)}{g(b) - g(a)} = \frac{f'(c)}{g'(c)} \qquad a < c < b$$
 (1)

We note first that $g(b) \neq g(a)$ For, if g(b) = g(a) we can apply Rolle's theorem to g(x), which shows that g'(x) must vanish within \mathfrak{A} , which is contrary to the hypothesis

To prove 1), we introduce the auxiliary function

$$h(x) = f(x) - f(a) - \frac{f(b) - f(a)}{g(b) - g(a)} \{g(x) - g(a)\}$$

Obviously h(x) is continuous in $\mathfrak A$ Also for points within $\mathfrak A$, for which f'(x) is finite,

$$h'(x) = f'(x) - \frac{f(b) - f(a)}{g(b) - g(a)}g'(x),$$

while for the other points within \mathfrak{A} , h'(x) is definitely infinite Finally, we observe that h(a) = h(b) = 0 We can thus apply Rolle's theorem to h(x), which gives 1) at once

449. 1. Let f(x), $f'(x) \cdots f^{(n-1)}(x)$, g(x), $g'(x) \cdots g^{(n-1)}(x)$ be continuous in $\mathfrak{A} = (a, a + \delta)$, and vanish for x = a. Let $f^{(n)}(x)$ be finite or infinite within \mathfrak{A} . Let $g^{(n)}(x)$ be finite and $\neq 0$ within \mathfrak{A} . Let g'(x), $g''(x) \cdots g^{(n-1)}(x) \neq 0$ within \mathfrak{A} . Then

$$\frac{f(a+h)}{g(a+h)} = \frac{f^{(n)}(c)}{g^{(n)}(c)} \cdot a < c < a+h.$$

$$\frac{f(a+h)}{g(a+h)} = \frac{f'(c_1)}{g'(c_1)}, \quad a < c_1 < a+h;$$
(1)

 $\frac{f'(c_1)}{g'(c_2)} = \frac{f''(c_2)}{g''(c_2)}, \quad a < c_2 < c_1, \quad \text{etc.}$

2. We note that the denominator g(a+h) in 1) is $\neq 0$. For otherwise, g'(x) would vanish somewhere within \mathfrak{A} .

The Form
$$\frac{0}{0}$$

450. 1. Let f(x), g(x) be continuous in R = RD(a), and vanish at a. Let g'(x) be finite, and $\neq 0$ within R. Let f'(x) be finite or infinite within R. Let

$$R \lim_{x=a} \frac{f'(x)}{g'(x)} = \lambda,$$
 finite or infinite. (1)

where x runs over only those values for which f'(x) is finite.

Then

$$R\lim_{x \to a} \frac{f(x)}{g(x)} = \lambda. \tag{2}$$

For, by 449,

For, by 448,

$$\frac{f(x)}{g(x)} = \frac{f'(\xi)}{g'(\xi)}, \qquad a < \xi < x.$$

The limit of the right side, as $x \doteq a$, is λ . Hence the limit * of the left side is λ , for x = a.

The reader should bear in mind that a limit is a general limit, unless the contrary is stated. Thus in 2), a runs over all values within R as it $\doteq \alpha$; while in 1) it ranges only over a specified part of R.

2 Let f(x), g(x) ranish at x-a while $g(x)\neq 0$ within RD(a)Let f'(a) exist finite or infinite Let g'(a) exist and be = 0 Then

$$R\lim_{\longrightarrow}\frac{f(x)}{g(x)}=\frac{f'(a)}{g'(a)}$$

For.

$$\frac{f(x)}{g(x)} = \frac{\frac{f(x) - f(a)}{x - a}}{\frac{f(x) - g(a)}{g'(a)}} = \frac{f'(a)}{g'(a)}$$

3 We can generalize 2 as follows

Let f(x) g(x) and their first n-2 derivatives be continuous in R=RD(a) Within R let $f^{(n)}(x)$ be finite or infinite $g^{(n)}(x)$ finite and d, g, $g^{(n)}(x)$ be finite or infinite, while $g^{(n)}(x)$ is expected at g(x) be finite or infinite, while $g^{(n)}(x)$ is finite and +0 Then

(2 For. by 419. $\frac{f(x)}{g(x)} = \frac{f^{(a-1)}(c)}{g^{\frac{a-1}{a-1}}(c)} = \frac{f^{(a-1)}(c) - f^{(a-1)}(a)}{g^{\frac{a-1}{a-1}}(c) - g^{\frac{a-1}{a-1}}(a)}$

But as x=a, so does c=a Hence, passing to the limit x=a, we get 2)

Example. Let

$$f(x) = x^1$$
 for rational x .

- 9 for strational z

Let

 $g(x) - \sin x$ Here f'(x) does not exact except at x=0 where it = 0. Hence, by 2,

$$R \lim_{x \to a} \frac{f(x)}{g(x)} \approx \frac{f(\theta)}{g(0)} - \frac{0}{1} = 0,$$

a result which is obvious from other cons derations.

4 In 1, we assume the existence of $\lambda = R \operatorname{lm} \frac{f'(x)}{g'(x)}$, and then show that

$$R \lim \frac{f(x)}{a(x)} = \lambda. \tag{1}$$

That the limit on the left side of 1) can exist when λ does not is shown by the example in 3. It is also illustrated by the following:

$$f(x) = x^2 \sin \frac{1}{x}, \text{ for } x \neq 0.$$

$$= 0, \quad \text{for } x = 0.$$

Let

$$g(x)=x.$$

Then, for $x \neq 0$,

$$f'(x) = 2x\sin\frac{1}{x} - \cos\frac{1}{x};$$

while

$$g'(x)=1.$$

Hence

$$\lambda = R \lim_{x \to 0} \frac{f'(x)}{g'(x)}$$

dees not exist. On the other hand,

$$\lim_{x\to 0}\frac{f(x)}{g(x)}=0.$$

We observe that this result also follows from 2.

451. Suppose:

1°.
$$f(x)$$
, $g(x)$ are continuous in $D(+\infty)$;

$$2^{\circ}$$
. $f'(x)$ is finite or infinite in D;

3°.
$$g'(x)$$
 is finite and $\neq 0$ in D;

4°.
$$f(+\infty) = g(+\infty) = 0$$
.

$$\lim_{x \to +\infty} \frac{f'(x)}{g'(x)} = \lambda, \qquad \lambda \text{ finite or infinite}$$

where x runs over only those values for which f'(x) is finite.

Then *
$$\lim_{x \to +\infty} \frac{f(x)}{g(x)} = \lambda.$$

We set

$$x=\frac{1}{u}$$
.

Then D goes over into $R = RD^*(0)$.

^{*} Cf. footnote, page 301.

Let

$$f(x) = f\left(\frac{1}{u}\right) = \phi(u),$$

$$g(x) = g\left(\frac{1}{u}\right) = \psi(u)$$

The functions ϕ , ψ not being defined for u = 0, we set

$$\phi(0) = \psi(0) = 0$$
 (1)

Since f g are continuous in D ϕ ψ are continuous in R, by yirtue of 1) and 4°

For points of D at which f (x) is finite,

$$\phi'(u) = \frac{df}{dz} \frac{dz}{dz} = -f'(z) \quad z^2$$

Hence at the corresponding points u in R, $\phi'(u)$ is finite. From the relation

$$\frac{\Delta \phi}{\Delta u} = \frac{\Delta f}{\Delta z} \frac{\Delta z}{\Delta u},$$

we see that when f'(x) is definitely infinite in D, $\phi'(u)$ is also infinite at the corresponding u point in R.

Thus $\phi'(u)$ is finite or infinite in R, while $\psi'(u)$ is finite and $\neq 0$ there

Then by 450, 1, 1f

$$R \lim_{n \to \infty} \frac{\phi'(u)}{\psi'(u)} = \lambda, \qquad \lambda \text{ finite or infinite}$$

u running over only those points for which $\phi'(u)$ is finite,

$$R \lim_{u \to 0} \frac{\phi(u)}{\psi(u)} = \lambda$$

But

$$R \lim_{x \to 0} \frac{\phi(x)}{\psi(x)} = \lim_{x \to \infty} \frac{f(x)}{\phi(x)}$$
 (1)

(2

Also

$$\lambda = R \lim_{x \to 0} \frac{\phi'(u)}{\psi'(u)} = \lim_{x \to \infty} \frac{x^2 f'(x)}{x^2 g'(x)} = \lim_{x \to \infty} \frac{f'(x)}{g'(x)}$$

Hence 1), 2) give the theorem

452. Let f(a+0), g(a+0) be infinite.

In R = RD(a) suppose that

1°. f(x), g(x) are continuous;

 2° . f'(x) is finite or infinite;

3°. g'(x) is finite and $\neq 0$.

Let

$$R \lim_{x=a} \frac{f'(x)}{g'(x)} = \lambda, \quad \lambda \text{ finite or infinite.}$$

x ranging over only those values for which f'(x) is finite.

Then *

$$R\lim_{x=a}\frac{f(x)}{g(x)}=\lambda.$$

Let $a < x < b < a + \delta$. Then, by 448,

$$\frac{a + \eta}{a + \xi} = \frac{a + \eta}{b + \delta}$$

$$\frac{f(x) - f(b)}{g(x) - g(b)} = \frac{f'(\xi)}{g'(\xi)}, \quad x < \xi < b.$$

Thus

$$f(x) = f(b) + \frac{f'(\xi)}{g'(\xi)} \{g(x) - g(b)\},\$$

whence

$$\frac{f(x)}{g(x)} = \frac{f(b)}{g(x)} + \frac{f'(\xi)}{g'(\xi)} \left\{ 1 - \frac{g(b)}{g(x)} \right\}. \tag{1}$$

Here b is any fixed point in R.

There are two cases according as λ is finite or infinite.

Suppose λ is finite. Let $\sigma > 0$ be small at pleasure; we can take δ so small that

$$\frac{f'(\xi)}{g'(\xi)} = \lambda + \sigma'. \qquad |\sigma'| < \sigma.$$

Let $\tau > 0$ be small at pleasure. We can choose $\alpha + \eta < b$, such that

$$\tau' = \frac{f(b)}{g(x)}, \qquad \tau'' = \frac{g(b)}{g(x)}$$

are numerically $<\tau$, if $x < a + \eta < b$.

^{*} Cf. footnote, page 301.

Then for all z in $(a^{\bullet}, a + \eta)$, we have by 1).

$$\frac{f(x)}{g(x)} = \tau' + (\lambda + \sigma')(1 - \tau'') \tag{2}$$

Thus

$$\left|\frac{f(x)}{g(x)} - \lambda\right| < \tau(1+|\lambda|) + \sigma(1+\tau) < \epsilon,$$

if a and 7 are taken sufficiently small

Suppose λ is infinite say $\lambda = +\infty$ Let M > 0 be large at pleasure We can choose & so small that

$$\frac{f'(\xi)}{\sigma(\xi)} = V(1+\mu) \qquad \mu > 0$$

Choosing n as before we have for every z in (a* a+n).

$$\frac{f(x)}{g(x)} = \tau' + M(1+\mu)(1-\tau'')$$

If we suppose \(\tau_{\frac{1}{2}}\) and M sufficiently large,

$$\frac{f(x)}{g(x)} > \mathcal{U}(1-\tau) - 1 > G, \quad \text{in } \mathcal{D}_{\tau}^{\bullet},$$

where G is as large as we please

453 Let
$$f(+\infty)$$
 $g(+\infty)$ be infinite

In D(+ 00), let

Let

1°
$$f(x)$$
 $g(x)$ be continuous,
2° $f'(x)$ be finite or infinite,

3°
$$g'(x)$$
 be finite and $\neq 0$

$$g''(x)$$
 be finite and $\neq 0$

 $\lim_{x \to \infty} \frac{f'(x)}{g'(x)} = \lambda, \qquad \lambda \text{ finite or infinite}$ Then

$$\lim_{x\to\infty} \frac{f(x)}{g(x)} = \lambda$$

We deduce this theorem from 452 in the same way as 451 was derived from 450

The Forms
$$0 \cdot \infty$$
, $\infty - \infty$, 0° , 1^{∞} , ∞°

454. 1. Let $f(x) \doteq 0$, $g(x) \doteq \pm \infty$. Then f(x)g(x) is of the form $0 \cdot \infty$.

Setting $fg = \frac{f}{1}$, this form is reduced to $\frac{0}{0}$.

2. Let $f(x) \doteq \pm \infty$, $g(x) \doteq \pm \infty$, the infinities having same signs. Then f(x) - g(x) is of the form $\infty - \infty$.

Setting

$$f - g = \frac{\frac{1}{g} - \frac{1}{f}}{\frac{1}{fg}},$$

this form is reduced to $\frac{0}{0}$.

3. Let $f \doteq 0$, $g \doteq 0$. Then $[f(x)]^{g(x)}$ is of the form 0°.

Let

$$y = f^g, \qquad f(x) > 0.$$

Then

$$\log y = g \log f = \frac{g}{\frac{1}{\log f}}$$

is of the form $\frac{0}{0}$.

$$\log y \doteq \lambda$$

then

$$\lim y = \lim \lceil f(x) \rceil^{g(x)} = e^{\lambda}.$$

The other forms 1^{∞} , ∞^0 are treated in a similar manner.

EXAMPLES

1. $x^{\mu}\log(1-\cos x), \quad \mu, \ x>0.$ (1)

has the form $0 \cdot \infty$ for x = 0. We may write it

$$\frac{\log(1-\cos x)}{x^{-\mu}},$$

which has the form $\stackrel{\infty}{\varpi}$. The conditions of 452 being satisfied, we differentiate numerator and denominator, getting as new quotient

$$-\frac{\sin x}{\frac{1-\cos x}{\mu x^{-(1+\mu)}}} = -\frac{1}{\mu} \frac{x^{1+\mu}}{\tan \frac{x}{2}}.$$

This has the form $\frac{0}{0}$, for z=0 Applying 450, 1, we get, differentiating once more,

whose limit for z=0, is 0

Hence,

$$R \lim_{x \to 0} x^x \log(1 - \cos x) = 0$$

12

 $R \lim_{n \to \infty} x^n \log x_i^n = 0 \qquad a, \mu > 0$

For, $x^{\mu}[\log x]^{\mu} = \frac{|\log x|^{\mu}}{\sqrt{2}} = \frac{f(x)}{\sqrt{2}}$

We apply 452

$$\frac{f(x)}{g^{\dagger}(x)} = \frac{\mu}{a} \frac{|\log x|^{\alpha-1}}{x^{-\alpha}}.$$

If $\mu \le 1$, this expression ≈ 0 If $\mu > 1$ we differentiate again, etc.

At first sight one might think that

$$\lim_{n \to \infty} \frac{f(n+1)}{f(n)} = 1,$$
(3)

since $\frac{n+1}{n} = 1$ This is however, not true to general

For example, let $f(z) = e^{z}$ Then

$$\frac{f(n+1)}{f(n)} = \frac{e^{n+1}}{e^n} = e.$$

Hence the limit 3) is here e and not 1 Again, let

Then $f(x) \Rightarrow e^{x}$

 $\frac{f(s+1)}{f(s+1)} = \frac{e^{s+1}}{s} = e^{sk_0-1}l_s$

which $-+\infty$

Criticisms

455 1 The treatment of indeterminate forms in many textbooks is deplorable

We consider some of the objectionable points in detail.

When f(x), g(x) vanish at x = a, the function

$$\phi(x) = \frac{f(x)}{g(x)} \tag{}$$

Some authors admit division by 0.

From this standpoint the value of ϕ at a is hidden because ϕ takes on the indeterminate form $\frac{0}{0}$. The true value, as such authors say, may often be found by a simple transformation, or by the method of limits.

For example, if

$$f(x) = x^2 - a^2$$
, $g(x) = x - a$,

the true value of ϕ may be found by removing the common factor x-a in

$$\frac{x^2-a^2}{x-a}=(x+a)\frac{x-a}{x-a}.$$

Thus

$$\phi(a)=2a.$$

As already remarked, division by 0 is ruled out in modern analysis.

First, because it is nowhere necessary; and secondly, because of the difficulties and ambiguities it gives rise to.

The expression 1) has then no value assigned to it for x=a. We may therefore, if we choose, agree that in all such cases ϕ shall have the value

 $\lim_{x \to a} \frac{f(x)}{g(x)}$

when this is finite. Some authors do this; in this case ϕ has a true value at a. However, we shall make no such convention in this work.

2. In this connection let us give an example of the so-called paradoxes which arise from division by 0.

Let
$$x = 1$$
; then $x^2 - 1 = x - 1$.

Dividing both sides by x-1, we get

$$x+1=1$$
.

which gives, since x = 1,

$$2 = 1$$
.

It is easy to see where the trouble arises.

When $e \neq 0$, we can always conclude from

$$ac = bc$$

(2

(3

that

$$a = b$$

If, however, c=0 we cannot always conclude 31 from 21 In fact, take $a \neq b$, if c = 0, we still have

ac = bc

1 To find $\lim \phi(x)$ some writers proceed thus From

$$\phi(a+h) = \frac{f(a+h)}{g(a+h)} = \frac{\frac{f(a+h)-f(a)}{h}}{\frac{f(a+h)-g(a)}{h}}$$

they conclude that

$$\lim \phi = \frac{f'(a)}{g'(a)}$$

This is correct if f'(a), g'(a) exist, and the latter is $\neq 0$ If both are 0, they say

$$\frac{f'(a)}{g'(a)}$$

$$\frac{f'(a)}{g'(a)}$$

is still indeterminate Applying the preceding reasoning to 2), it follows that its true value is that of

 $\frac{f''(a)}{g''(a)}$

This last step would be permissible, provided the first step showed that (3

$$\lim \phi = \lim \frac{f'(x)}{g'(x)}$$

But it does not it shows only that 1) is true, and even here

we must assume that $q'(a) \neq 0$ In order to take this second step correctly, we have proved

Cauchy's theorem, 448 Cf 449, 450,

2. In this connection we note that we cannot always say that

$$\frac{f(x)}{g(x)}$$
 and $\frac{f'(x)}{g'(x)}$

have the same limit for x = a, when f(a) = g(a) = 0.

For example, let

$$f(x) = x^2 \sin \frac{1}{x}, \ g(x) = x.$$
 $a = 0.$

Then

$$\lim_{x \to 0} \frac{f(x)}{y(x)} = 0,$$

while

$$\frac{f'(x)}{g'(x)} = 2x \sin \frac{1}{x} - \cos \frac{1}{x}$$
 $x > 0$.

has no limit for x = 0. Cf. 450.

457. Some writers, using the relation of Cauchy,

$$\phi = \frac{f(x)}{g(x)} = \frac{f'(c)}{g'(c)}, \quad a < c < x.$$

conclude now that

$$\lim \phi = \frac{f'(a)}{g'(a)}.$$

This is true if f'(x), g'(x) are continuous at a, and $g'(a) \neq 0$.

458. Some writers, in order to evaluate $\lim \phi$, develop f(x), g(x) into infinite power series. The possibility of such a development is established only for a few simple eases in many text-books. For example, such books do not show that

see
$$x$$
, $\tan x$, $e^{\sin x}$

can be developed into power series; yet they give examples of indeterminate forms involving these functions.

There is, however, no necessity of using infinite series; all that is needed for such eases is <u>Taylor's development in finite</u> form. See 445, 446.

459 To evaluate the form some writers proceed thus.

$$\phi(x) = \frac{f(x)}{g(x)} = \frac{\frac{1}{g(x)}}{\frac{1}{f(x)}}$$

Hence

$$\lim \phi(x) = \lim \frac{\frac{g'(x)}{g'(x)}}{\frac{f'(x)}{f'(x)}} = \lim \phi^{3}(x) \frac{g'(x)}{f(x)}$$

Dividing by $\lim \phi(x)$, they get

$$1 = \lim \phi(x) \frac{g'(x)}{f(x)}$$

Непсе

$$\lim \phi(x) = \lim \frac{f'(x)}{g'(x)}$$

This method assumes the existence of $\lim \phi(x)$, that is, the existence of the very thing we are seeking is put in question Suppose by this method we find that

$$\lim \frac{f'(x)}{g(x)} = 1$$

for example, what right have we to say that therefore

$$\lim \frac{f(x)}{q(x)} = 1?$$

None whatever, until by some subsidiary investigation, the existence of $\lim \phi$ is established See 377, 8

Scale of Infinitesimals and Infinities

460 Consider the functions

$$f(x) = \log^{\alpha} x$$
 $g(x) = x^{\beta}$, $\alpha, \beta > 0$

Both increase indefinitely as $x = +\infty$ We may ask which increases faster

The quotient

$$Q = \frac{f(x)}{g(x)}$$

is of the form $\frac{\infty}{\infty}$. The conditions of 453 being satisfied, we eonsider

$$Q_1 = \frac{f'(x)}{g'(x)} = \frac{n}{\beta} \frac{\log^{\alpha - 1} x}{x^{\beta}}$$

If $0 < \alpha \le 1$, $Q_1 \doteq 0$; hence $Q \doteq 0$.

If $\alpha > 1$, we consider

$$Q_2 = \frac{f''(x)}{g''(x)} = \frac{\alpha \cdot \alpha - 1}{\beta^2} \frac{\log^{\alpha - 2} x}{x^{\beta}}.$$

Thus if $0 < \alpha \le 2$, $Q_2 \doteq 0$; hence $Q \doteq 0$.

If $\alpha > 2$, we may continue this process. As the exponent α is diminished by unity each time, $\log x$ must have finally a negative or zero exponent. Thus in every case $Q \doteq 0$.

461. 1. Let f(x), g(x) become infinite for $x \doteq a$, a being finite or infinite. If

$$\lim \frac{f(x)}{g(x)}$$
 is finite and $\neq 0$,

we say f and g are of the same order infinite. If

$$\lim \frac{f(x)}{g(x)} = 0,$$

we say f is of lower order infinite than g. If

$$\lim \frac{f(x)}{g(x)}$$
 is infinite,

we say f is of higher order infinite than g.

These three eases are denoted respectively by

$$f(x) \sim g(x), f(x) < g(x), f(x) > g(x).$$

We may also say more briefly, that f(x) is infinitarily equal, less than, greater than g(x).

2 Similar definitions hold when

$$f(x) = 0, \quad g(x) = 0.$$

lf, for example,

$$\lim \frac{f(x)}{g(x)} = 0,$$

we say f(x) is infinitely small relative to g(x), or an infinitesimal of higher order than g(x) We may also say f(x) is infinitarily smaller than g(x) In symbols,

f(x) < g(x)

3 Turning to the result of 469, we have
$$\log^2 x < x^2 \quad \text{a. } \beta > 0, x = +\infty.$$

however large a is and however small B

462 Let us consider now functions of the type

1,x, 1,x, 1,x 1,x

$$x>l_1x>l_2x > l_nx$$

The values of these sterated logarithms decrease very rapidly For example, let $x \approx 1,000,000,000 \simeq 10^{\circ}$

Then

$$l_1x = 20723$$
, $l_2x = 3031$ $l_2x = 1108$, $l_2x = 0103$

 $I_n x = a$ negative number.

Hence Lz does not exist

463 1 When $x = +\infty$, we have, if $a_1 a_2, a_3 > 0$,

$$x > l_1 = x > l_2 = x > l_3 = x$$
 (8

The sequence S may be called the logarithmic scale

To prove S, let

$$u = l_{m-1}x$$
.

Then $u \doteq +\infty$ with x. We have

$$\lim_{x \to +\infty} \frac{l_m^{a_m} x}{l_{m-1}^{a_{m-1}} x} = \lim_{u \to +\infty} \frac{\log^{a_m} u}{u^{a_{m-1}}} = 0, \qquad m = 1, 2, \dots$$

by 461, 3.

2. If
$$\alpha_1, \alpha_2, \dots > 1, x = +\infty$$
;

$$l_1{}^{a_1}\!x \!> l_1xl_2{}^{a_2}\!x \!> l_1xl_2xl_3{}^{a_3}\!x \!> \cdots$$

This follows at once from 1.

464. Let
$$x = +\infty$$
, while α , α_1 , α_2 , $\dots > 0$. Then

$$x^{a} < (e^{1})^{a_{1}} < (e^{e^{x}})^{a_{2}} < (e^{e^{x}})^{a_{3}} < \cdots$$
 (T

The sequence T may be called the exponential scale.

Let

$$f(x) = x^{a}, \ g(x) = e^{a_{1}x}, \ Q = \frac{f(x)}{g(x)}$$

We apply 453.

$$\frac{f'(x)}{g'(x)} = \frac{\alpha x^{a-1}}{\alpha_1 e^{a_1 x}}.$$

If now $0 < \alpha < 1$, Q = 0.

If $\alpha > 1$,

$$\frac{f''(x)}{g''(x)} = \frac{\alpha(\alpha-1)x^{\alpha-2}}{\alpha_1^2 e^{a_1 x}}.$$

If $1 < \alpha \le 2$, this shows that $Q \doteq 0$, and so on.

Hence

$$x^{a} < (e^{x})^{a_1}$$

To show

$$(e^x)^{\alpha_1} < (e^{e^x})^{\alpha_2}, \tag{1}$$

let us set

$$u=e^x$$
.

Then

$$\lim_{x \to +\infty} \frac{(e^x)^{a_1}}{(e^{e^x})^{a_2}} = \lim_{u \to +\infty} \frac{u^{a_1}}{(e^u)^{a_2}} = 0,$$

as just shown. This proves 1). The rest of the theorem follows now in the same way.

Order of Infinitesimals and Infinities

465 1 Let x = 0, then x is an infinitesimal, x2, x2 are also

infinitesimals

Taking x as a standard, we may say x^* is an infinitesimal of order n, n being a positive integer, and, in general, if x > 0, x^* is an infinitesimal of order μ , where μ is any positive number,

Then, if

$$R \lim_{x \to \infty} \frac{f(x)}{x^*}$$

is finite and ± 0 we say that f(x) is an infinitesimal of order μ . Not every infinitesimal, however, has an order

For example, by 464, there is no number it, such that

$$R \lim_{x \to \infty} \frac{e^{-\frac{1}{x}}}{x^2}$$

is not 0 Hence e has no order

2. On the other hand, an infinitesimal f(z) may not have an order μ , because

$$R \lim_{x \to \infty} \frac{f(x)}{x^n}$$

either does not exist, or when it does it is infinite or zero

There

$$R \lim_{x \to \infty} \frac{x \sin \frac{1}{x}}{x}$$

does not exast Henc

is an infinitesimal without an order

3 Obviously, similar remarks hold for infinities

CHAPTER XI

MAXIMA AND MINIMA

ONE VARIABLE

Definition. Geometric Orientation

466. Let f(x) be defined in $\mathfrak{A} = (a, b)$. Let c be an inner point of \mathfrak{A} . If $\Delta f = f(x) - f(c) > 0$ in $D^*(c)$, (1

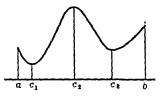

f has a minimum at c. If

$$\Delta f = f(x) - f(c) < 0 \text{ in } D^*(c), \tag{2}$$

f has a maximum at c.

In words, we may say: f has a maximum at c when f(c) is

greater than any other value of f in the domain of c; it has a minimum at c when f(c) is less than any other value of f in the domain of c. According to this definition, f(x), whose graph is given in the figure, has a maximum at c_3 , and a minimum at c_1 , c_3 .

The reader should not confuse the terms f(x) has a maximum or a minimum at a point c, with the terms

$$\operatorname{Min} f(x)$$
, $\operatorname{Max} f(x)$, in \mathfrak{A} .

A function may nave an infinite number of extremes, that is, maxima or minima, in A.

Example.

$$f(x) = x^{2} \left(1 + \sin^{2} \frac{1}{x} \right), \quad \text{for } x \neq 0,$$

$$= 0. \quad \text{for } x = 0.$$

This function oscillates between the two parabolis

$$y-z^2 \qquad y=2\,z^2$$

At the origin f has a minimum and in any vic pity of the origin f has an infinite number of maxima and minima.

467 We consider now how the points at which f(x) has an extreme may be determined. Consulting the Fig. in 466 the reader will observe that at the points of extreme the tangent is parallel to the axis of x that is at these points f'(x) = 0

However f(x) does not need to have an extreme at all the points at which f(x) = 0

For example

$$y = x^3$$

This is an increasing function whose derivative vanishes at x=0 In fact at this point the graph has a point of inflection with a tangent parallel to the x axis See Fig 1

On the other hand not all the joints of extreme are given by the roots of f'(z) = 0

Example

$$y = x^{\frac{1}{2}}$$

This function has a minimum at the origin θ which is a cuspidal point with vertical tangent See Fig. 2

At this point y has no differential coefficient, since

$$Rf(0) = +\infty$$
 $Lf(0) = -\infty$

Criteria for an Extreme

468 1 In D(a) let $f^m(z)$ be continuous and $f^m(a) \neq 0$ Let

$$f(a)=f'(a)= =f^{(a-1)}(a)=0$$

Then f has no extreme at a if n is odd. If n is even, it has a min mum if $f^*(a)>0$ a maximum if $f^*(a)<0$

For, under these conditions, we have

$$\Delta f = f(a+h) - f(a) = \frac{h^n}{n!} f^{(n)}(a+\theta h).$$

Since $f^{(n)}(x)$ is continuous at a,

 $\operatorname{sgn} f^{(n)}(a + \theta h) = \operatorname{sgn} f^{(n)}(a) = \sigma.$ $\operatorname{sgn} \Delta f = \sigma \operatorname{sgn} h.$

If n is odd,

As h can take on positive and negative values, Δf does not preserve one sign in $D^*(a)$. Hence, f has no extreme at a. If n is even,

 $\operatorname{sgn} \Delta f = \sigma.$

Thus in D^* ,

$$\Delta f > 0$$
, if $f^{(n)}(a) > 0$,
< 0, if $f^{(n)}(a) < 0$.

2. In $\mathfrak{A} = (a, b)$, let f'(x) exist, finite or infinite. The points within \mathfrak{A} at which f(x) has an extreme, lie among the zeros of f'(x).

For, suppose f(x) has a maximum at c. Then for h > 0,

$$f(c+h)-f(c)<0, f(c-h)-f(c)<0.$$

Thus,

$$R = \frac{f(c+h) - f(c)}{h} < 0, \ L = \frac{f(c-h) - f(c)}{-h} > 0.$$
 (1)

But when $h \doteq 0$,

$$\lim R = \lim L = f'(c). \tag{2}$$

On the other hand, 1) shows that

$$\lim R \stackrel{=}{\sim} 0$$
, $\lim L \stackrel{=}{\sim} 0$;

which with 2) shows that f'(c) = 0.

3. The reasoning in 2 also shows:

If f(x) has an extreme at x = a, then f'(a) = 0, if f'(a) exists

220

469 Let f(x) be continuous in D(a) Let f'(x) be finite in Do(a) Let

$$Rf'(a) = \sigma \varphi$$
, $Lf'(a) = -\sigma \infty$, $\sigma = \pm 1$

Then f has a minimum at a, if $\sigma = +1$, and a maximum, if $\sigma = -1$

To fix the ideas, let $\sigma = +1$

asdT

$$R\lim_{k\to\infty}\frac{f(n+k)-f(a)}{k}=+\infty,$$

$$R\lim_{n\to\infty}\frac{f(a-h)-f(a)}{-h}=-\infty$$

Thus there exists a \$>0 such that

$$f(a+h)-f(a)>0$$
, $|h|<\delta$

in Di*(a) Hence f has a minimum at a

470 Let f(x) be continuous in D(a) In D*(a), let f'(x) be finite or infinite and never vanish throughout any interval of it In RD*(a), let f'(x) be positive when not zero, in LD*(a), let f'(x) be negative when not zero. Then f(x) has a minimum at a. If these signs are reversed f has a maximum

For, using 403, we see that f(x) is an increasing function in RD(a), and a decreasing function in LD(a) Hence f has a tammum at a

EXAMPLES

 $f(x) = a + x^{\frac{1}{2}}$

471 In 388 we saw

 $Rf'(0) = +\infty$ $Lf'(0) = -\infty$

Hence by 469 f has a minimum at 0, a result which may be seen directly

 $f(x) = \frac{x^2 - 1}{1}$, for $x \neq 0$, 472

This function was considered in 386. Applying 470, we see that f has a municipum at the origin a result that may be seen directly

473. Let
$$f(x) = e^{-\frac{1}{x^2}}$$
, for $x \neq 0$,
= 0, for $x = 0$.

This function is Cauchy's function. We see directly that it has a minimum at the origin. The same result is obtained by 470.

Criticism

474. Some writers confound the terms the function has a maximum or minimum at a point, with the terms maximum or minimum of a function in an interval. These two terms may or may not mean the same thing.

For example, let

$$f(x) = \sin x, \qquad \mathfrak{A} = (0, 2\pi).$$

Then f has a maximum at $\frac{\pi}{2}$, and a minimum at $\frac{3\pi}{2}$. These are also the maximum and minimum of f in \mathfrak{A} . On the other hand, if we take $\mathfrak{B} = \left(0, \frac{\pi}{2}\right)$ as one interval, f has neither a maximum nor a minimum at any point in \mathfrak{B} ; yet its maximum in \mathfrak{B} is 1, and its minimum in \mathfrak{B} is 0.

475. The following example also illustrates this point.

Find the greatest and least distance δ between a fixed point A within a circle and any point P on the circle.

Let the circle be

$$x^2 + y^2 = r^2,$$

and the coördinates of A be a, 0; a > 0.

Then

$$\delta = \sqrt{(x-a)^2 + y^2} = \sqrt{a^2 + r^2 - 2ax}$$

and

$$\frac{d\delta}{dx} = \frac{-a}{\sqrt{a^2 + r^2 - 2ax}} < 0.$$

Hence δ is a decreasing function in $\mathfrak{A} = (-r, r)$, and has no maximum or minimum at any point in \mathfrak{A} . It has, however, a maximum and a minimum in \mathfrak{A} , viz.

Max
$$\delta = \overline{AC}$$
, Min $\delta = \overline{AB}$.

1 f

SEVERAL VARIABLES

Definite and Indefinite Forms

476 1 Let $f(x_1 x_m)$ be defined over a region, of which a is a point

$$\Delta f = f(x) - f(a) > 0, \quad \text{in } D^*(a),$$

f has a minimum at a II

$$\Delta f < 0$$
, in $D^{\bullet}(a)$,

f has a maximum at a

The theorem of 468 may be generalized thus

Let the partial derivatives of $f(z_1 - z_n)$ of order n+1 be continuous in D(a). Let the partial derivatives of order < n vanish at a while the lerivatives of order n do not all vanish at a. Then y

n so odd f has no extreme at a

Let n bo even: If $d^{*}f(a) > 0$ in $D^{*}(a)$ f has a minimum, if it is < 0, it has a maximum at a If $d^{*}f(a)$ has both signs in $D^{*}(a)$, f has no extreme at a.

Let $z_1 = a_1 + h$, $z_2 = a_2 + h$. Then

$$\Delta f = \frac{1}{a} d^a f(a) + \frac{1}{a+1} d^{a+1} f(a+\theta \lambda),$$

by 434

Let η_1 η_m be the direction cosines [244 4] of the line L join $\log a$ and x. Then

$$h_i = r\eta_1$$
 $h_m = r\eta_m$

where

$$\tau = \sqrt{h_1^2 + + h_n^2} \quad \eta_1^2 + + \eta_n^2 = 1$$

Then $\Delta f = r^{\mu}H(\eta) + r^{\mu+1}K(\eta)$,

since $d^{s}f d^{s+1}f$ are homogeneous in h_1 , h_n . Since the derivatives of order n+1 are continuous in $D_{\delta}(a)$, there exists a positive number G, such that

$$|K| < G$$
, in $D_i(a)$

If now $d^n f(a) > 0$ in $D^*(a)$, H is > 0 on the sphere

$$\eta_1^2 + \dots + \eta_m^2 = 1,$$
 (8)

to which η is restricted.

Then, by 355, 2, there exists a $\lambda > 0$, such that

$$H > \lambda$$
.

Then, by virtue of 1), we can choose $\delta' < \delta$ so small that

$$\Delta f > 0$$
, in $D_{\delta'}^*(a)$.

Hence f has a minimum at a.

Similar reasoning shows that if $d^n f(a) < 0$, f has a maximum.

Consider now the case that $d^n f(a)$ has both signs in $D^*(a)$. Suppose that it is positive at a + h and negative at a + k.

Let L, M be the lines joining these points with a. Let η , κ be their direction cosines. Let

a q+th a+h L

$$H(\eta) = A,$$
 $A > 0.$
 $H(\kappa) = B.$ $B < 0.$

Let a+th, 0 < t < 1, be a point on L between a and a+h.

Let

Dist(a, a + h) = r; then Dist(a, a + th) = tr.

Thus

$$\Delta f = f(a+th) - f(a) = t^n r^n \{A + tr K'\}.$$

Let t_0 be such that

$$t_0 rG < A$$
.

Then, by 1), $\Delta f > 0$ for all points on L between a and $a + t_0 h$, a excluded. Similar reasoning shows that $\Delta f < 0$ for all points on M sufficiently near a, the point a excluded.

Thus in any domain of a, however small, Δf has opposite signs. Hence in this case f has no extreme at a.

Let n be odd. Then H being homogeneous,

$$H(-\eta) = (-1)^{\eta} H(\eta) = -H(\eta).$$

Hence $d^n f(a)$ has opposite signs in every domain of a. Hence when n is odd, f has no extreme at a.

2 Let f(x, xn) have partial derivatives of the first order, finite or infinite, in the region R

The points of R, at which f has an extreme, satisfy the system of equations

$$\frac{\partial f}{\partial x_1} = 0 \quad \cdot \quad \frac{\partial f}{\partial x_m} = 0$$

The demonstration is analogous to that of 468, 2

477 1 We have just seen that the sign of def(a) plays a decisive rôle in questions of maxima and minima. But as already observed, def is a homogeneous integral rational function of he h. h. of degree n Such functions are subjects of study in algebra and the theory of numbers, where they are often called

forms A form $\Phi(x, x_n)$ which has always one sign, except at the origin where it necessarily vanishes, is called definite

Such a form is

$$a_1^2 x_1^2 + + a_m^2 x_m^2$$

(1

the a's being not all 0

If the sign of a definite form is positive, it is called a positive definite form, if negative, it is a negative definite form. Thus 1) is a positive definite form, while

$$-a_1^2x_1^2--a_m^2x_m^2$$

is an example of a negative definite form

If & can take on both signs, it is called indefinite. Thus

is an indefinite form.

$$x_1^2 + + x_n^2$$

There is a class of forms which vanish at points besides the origin and yet, when not 0, have always one sign. They are called semidefinite forms Such a form is, for example,

$$(a_1x_1 + a_nx_n)^2$$

which is positive when not 0

Consider the quadratic form

$$F = Ax^2 + 2Bxy + Cy^4.$$

If $A \neq 0$, we can write it

$$F = \frac{1}{A} \left\{ (Ax + By)^2 + (AC - B^c)y^2 \right\}.$$

If the determinant

$$D = AC - B^2$$

is > 0, F does not vanish except at the origin, and is therefore a positive definite form if A > 0, and a negative definite form if A < 0.

If D < 0, F is an indefinite form.

If D=0,

$$F = \frac{1}{A} \left(Ax + By \right)^2.$$

Hence F vanishes on the line

$$Ax + By = 0,$$

but has otherwise one sign. Thus, in this case, F is semidefinite.

2. The theorem of 476 may now be stated as follows: If $d^n f(a)$ is an indefinite form, f has no extreme at a. If it is a positive definite form, f has a minimum; if it is a negative definite form, f has a maximum at a.

478. When n=2, i.e. when not all partial derivatives of the second order are 0 at a, $d^n f(a)$ becomes a quadratic form,

 $d^2f(a) = \sum a_{i\kappa}h_ih_{\kappa}; \qquad \iota, \ \kappa = 1, \ 2, \ \cdots \ m. \tag{1}$

where

$$a_{ix} = f^{\prime\prime}_{z_i x_i} (a_1 \cdots a_m),$$

and hence

$$a_{i\kappa} = a_{\kappa i}$$
.

The determinant

$$\Delta_{m} = \begin{vmatrix} a_{11} & a_{12} & \cdots & a_{1m} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mm} \end{vmatrix}$$

is called the determinant of the form 1).

Let Δ_{m-1} be obtained by deleting the last row and column in Δ_m ; let Δ_{m-2} be obtained by deleting the last two rows and columns in Δ , etc.; finally, let $\Delta_0 = 1$.

In algebra the following theorem is proved:

In order that the form

$$\sum_{k,\kappa} a_{i\kappa} h_i h_{\kappa} \tag{2}$$

be a positive definite form, it is necessary and sufficient that the signs of

 $\Delta_0, \Delta_1, \cdots \Delta_m$ (3)

are all positive 1 or 2) to be a definite negative form it is necessary and sufficient that the signs in 3) are alternately positive and negative

Applying this result to the theorem in 476, we have

Let the partial derivatives of the third order be continuous in D(a), and let those of the second order not all vanish at a Let all the first derivatives ranish at a Let

$$a_{\omega} = f^{tt}_{x, r_{\alpha}}(a_1 \quad a_{\omega}),$$

$$\Delta_{\tau} = \begin{vmatrix} a_{11} & a_{tr} \\ a_{1} & a_{1} \end{vmatrix} \qquad r = 0, 1, \quad m$$

$$\Delta_{0} = 1.$$

If the signs in the sequence

are all positive, f has a minimum. If the signs in this sequence are alternately positive and negative, f has a maximum at a

Semidefinite Forms

479 Up to the present, the rase that d'f(a) is a semidefinite form has not been treated. It is, however, easy to show that in this case f may or may not have an extreme at a.

Es. 1.
$$f(xy) = x^3 - 6xy^3 + 8y^4 = (x - 2y^3)(x - 4y^3)$$

$$f'_*(0) = 0 \quad f'_*(0) = 0$$

$$f^{\prime\prime}_{\rm el}(0) \simeq 2 \quad f^{\prime\prime}_{\rm ep}(0) \simeq 0, \quad f^{\prime\prime}_{\rm el}(0) \simeq 0$$
 Hence

We have here a semidefinite form.

That f has not an extreme at the origin is

That f has not an extreme at the origin obvious.

For if P is the parabola

and Q the parabola
$$x = 2y^2$$
, $x = 4y^2$.

we see that f < 0 between these parabolas, and > 0 in the rest of the plane, norms on the parabolas excepted, as in the figure

Ex. 2.

$$f(xy) = y^{2} + x^{2}y + x^{4}$$

$$= \left(y + \frac{x^{2}}{2}\right)^{2} + \frac{3}{4}x^{4}.$$

$$a = (0, 0).$$
(1)

Obviously, from 1), f has a minimum at the origin.

Here

$$f_x'(0) = 0, \quad f_y'(0) = 0.$$

Hence,

$$f_{xy}^{\prime\prime}(0) = 0$$
, $f_{xy}^{\prime\prime}(0) = 0$, $f_{yz}^{\prime\prime}(0) = 2$.
 $d^2f(0) = k^2$.

We have here a semidefinite form.

480. It is beyond the scope of this work to do more than show that the semidefinite case is ambiguous and requires further investigation. We refer the reader for a detailed treatment of this case to Stolz, Grundzüge, Vol. 1, p. 211 seq.; Jordan, Cours., Vol. 1, p. 380 seq.; Scheeffer, Math. Ann., Vol. 35, p. 541; v. Dantscher, Math. Ann., Vol. 42, p. 89.

Criticism

481. The partial derivatives of order n being continuous in D(a), we have seen that

$$\Delta f = df(a) + \frac{1}{2!} d^2 f(a) + \dots + \frac{1}{n!} d^n f(a + \theta h) = T_1 + T_2 + \dots + T_n.$$

The terms T_1 , T_2 , ... are polynomials in h_1 , h_2 , ... h_m of 1°, 2°, ... degree, whose coefficients, except the last, are constant. Letting h_1 , h_2 , ... be infinitesimals of the 1° order, T_r if $\neq 0$ is thus an infinitesimal of rth order. The assumption is now made by many authors that if r < s, then T_r is infinitely small compared with T_r . When there is only one variable h, this is indeed true; it is not, however, always true when there are two or more variables h_1 , h_2 , ...

As an example, consider the form

$$h_1^2 - 6 h_1 h_2^2 + 8 h_2^4 = T_2 + T_3 + T_4$$

Let the increments A, A, be related by the equation

$$h_2^3 = h_1$$
, (1)

: e let the point (h1, h2) approach the origin along the parabola 1) Then

$$T_2 = h_2^4$$
 $T_2 = -6h_2^4$ $T_4 = 8h_2^4$,

which shows that T' T instead of being infinitely small compared with T., are in fact numerically 6 and 8 times larger than T.

482 Let us see now how this erroneous assumption regarding infinitesimals, when applied to the semidefinite case, leads to a false result . For simplicity we take only two variables z, y

Let

$$\Delta f = f(a+h,b+k) - f(a,b)$$

$$= \frac{1}{2!} [Ah^2 + 2Bhk + Ch^2] +$$

$$= T_2 + T_3 +$$

Let the determinant $AC - B^2 = 0$ Then T_a is a semidefinite form To fix the ideas let A = 0, then

$$T_2 = \frac{1}{2A} \{Ah + Bk\}^2$$
, by 477, 1

Thus Δf has the sign of A, except for the points (h, k) on the line L. Ax + By = 0

$$x + By = 0 (L$$

For points on L, Af becomes

$$T_3 + T_4 +$$

For points on the line L, on opposite sides of the origin, T, takes on opposite signs. As the sign of Af at these points depends on the sign of T. (making use of the above erroneous assumption) it is thus necessary that $T_2 = 0$ for points on L if f is to have an extreme at a, b If T = 0 for these points.

$$\Delta f = T_1 +$$

for these points. If now $T_4 \neq 0$ on L, f has an extreme * at (a, b), if T_4 has the same sign as A, for points of L, the origin excluded.

That this result is wrong may be shown by applying it to

$$f(xy) = x^2 - 6xy^2 + 8y^4,$$

which we considered in 479, Ex. 1.

Here

$$T_2 = h^2$$
, $T_3 = -6 hk^2$, $T_4 = 8 k^4$, $A = 2$.

The line L is, in this case, the y-axis. For points on L, $T_3 = 0$; while $T_4 > 0$, the origin excepted. Thus T_4 has the same sign as A. We should have therefore an extreme at the origin, if the above reasoning were correct. But as we already saw in 479, f has no extreme at the origin.

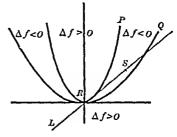

483. Another error which is sometimes made is the following. It is assumed that the function f(x, y) has an extreme at the point R when and only when f has an extreme along every right line through R.

That this view is incorrect is seen by the function

$$f(xy) = (x - 2y^2)(x - 4y^2),$$

given in 479, Ex. 1.

As the figure shows, a point S moving along any line L toward the origin R, finally remains in a region for which $\Delta f > 0$, the origin of course excluded. If, therefore, this view were correct, f would have a minimum at R, which we know is not true.

Relative Extremes

484. 1. Let us consider the problem of finding the points of maxima and minima of a function

$$w = f(x_1 \cdots x_m, u_1 \cdots u_p); \tag{1}$$

According to the above erroneous hypothesis.

where the variables u_1 u_p are one valued functions of x_1 x_m defined over a region R and satisfying the system

$$\phi_1(x_1 \quad v_p) = 0$$

$$\phi_2(x_1 \quad v_p) = 0$$
(2)

Such points of maxima and minima are called points of relative extreme to distinguish them from the case when the variables $x_1 \quad x_n \quad u_1 \quad u_n$ are all independent

Let the point (x_1, u_s) run over the region T when (x_1, x_s) runs over R. Let $f_s \phi_s \phi_s$ have continuous first partial derivatives with respect to x_1, u_s in T and let the us have continuous first partial derivatives with respect to x_1, x_s in R

Let w considered as a function of z, z, be denoted by

$$w = F(z, z_n)$$

The points of extreme of ω in R satisfy the system

$$\frac{\partial F}{\partial x_1} = 0 \qquad \frac{\partial F}{\partial x_n} = 0, \tag{8}$$

by 476 2. Let S denote the set of points determined by 3). Lagrange has given a method for forming the system 3), which is often aerviceable. It rests on the introduction of certain undetermined multipliers μ_1 , μ_p . In fact, differentiating 1) 2) we get

$$\begin{split} dw &= \frac{\partial^2}{\partial x} \, dx_1 + \quad + \frac{\partial^2}{\partial x_n} dx_n + \frac{\partial^2}{\partial x_1} du_1 + \quad + \frac{\partial^2}{\partial x_p} du_p \,, \\ d\phi_1 &= \frac{\partial \phi_1}{\partial x_1} dx_1 + \quad + \frac{\partial \phi_2}{\partial x_p} dx_n + \frac{\partial \phi_1}{\partial x_p} du_p + \frac{\partial \phi_2}{\partial x_p} du_p = 0 \,, \\ d\phi_p &= \frac{\partial \phi_2}{\partial x_1} dx_2 + \quad + \frac{\partial \phi_2}{\partial x_2} dx_2 + \frac{\partial \phi_2}{\partial x_2} du_1 + \quad + \frac{\partial \phi_2}{\partial x_2} du_p = 0 \,. \end{split}$$

Multiply the 2d, 3d, equations by μ_1 , μ_2 , respectively, and add the results to the first equation

We get
$$dw = \left(\frac{\partial f}{\partial x_1} + \sum \mu_r \frac{\partial \phi_r}{\partial x_n}\right) dx_1 + + \left(\frac{\partial f}{\partial u} + \sum \mu_r \frac{\partial \phi_r}{\partial u}\right) du_r$$

Let us now, if possible, determine the μ 's so that

$$\frac{\partial f}{\partial u_1} + \sum_{r} \mu_r \frac{\partial \phi_r}{\partial u_1} = 0, \quad \cdots \quad \frac{\partial f}{\partial u_p} + \sum_{r} \mu_r \frac{\partial \phi_r}{\partial u_p} = 0.$$
 (5)

Then 4) gives

$$dw = \left(\frac{\partial f}{\partial x_1} + \sum \mu_r \frac{\partial \phi_r}{\partial x_1}\right) dx_1 + \dots + \left(\frac{\partial f}{\partial x_m} + \sum \mu_r \frac{\partial \phi_r}{\partial x_m}\right) dx_m. \tag{6}$$

Then, by 429, 2,

$$\frac{\partial F}{\partial x_1} = \frac{\partial f}{\partial x_1} + \sum \mu_r \frac{\partial \phi_r}{\partial x_1}, \quad \cdots \quad \frac{\partial F}{\partial x_m} = \frac{\partial f}{\partial x_m} + \sum \mu_r \frac{\partial \phi_r}{\partial x_m}.$$

These are the left hand members of the equations 3). Hence, by 3),

$$\frac{\partial f}{\partial x_1} + \sum_{r} \mu_r \frac{\partial \phi_r}{\partial x_1} = 0, \quad \cdots \quad \frac{\partial f}{\partial x_m} + \sum_{r} \mu_r \frac{\partial \phi_r}{\partial x_m} = 0.$$
 (7)

Thus the points of S are determined by 2), 5), 7).

2. Let us introduce the function

$$g = f + \mu_1 \phi_1 + \dots + \mu_p \phi_p.$$

We observe that, considering $x_1 \cdots u_p$ as independent variables,

$$\frac{\partial g}{\partial x_1} = 0, \quad \cdots \quad \frac{\partial g}{\partial x_m} = 0, \quad \frac{\partial g}{\partial u_1} = 0, \quad \cdots \quad \frac{\partial g}{\partial u_p} = 0$$
 (8)

are precisely the equations 5), 7).

485. To determine whether a point of S is a point of extreme, it is often necessary to consider the second and even higher differentials of $F(x_1 \cdots x_m)$. Here it is sometimes convenient to make use of the fact that

$$d^2F = d^2g;$$

where the differential on the right is calculated supposing

$$x_1 \cdots x_m, u_1 \cdots u_p$$

to be independent variables.

For, let us denote a considered as a composite function of x by $G(x_1 x_n)$. Then

$$F(x, x_n) = G(x, x_n),$$

since the d's vanish now by 484, 2

Hence

$$d^2F = d^2G$$

But. by 433, 2).

$$d^{n}G = d^{n}g + \sum_{i} \frac{\partial g}{\partial x_{i}} d^{n}x_{i} + \sum_{i} \frac{\partial g}{\partial u_{i}} d^{n}u_{i}$$

$$=d^{3}g$$
, by 484, 8)

486 Example Let us find the abortest distance from the point P = (aigsts). to the plane (1

 $a = b_1 x_1 + b_2 x_3 + b_3 x_4 + b_6 = 0$ Let

$$w = \delta^2 = \Sigma (x_i - a_i)^2$$
 $i = 1, 2, 3$

The points of minimum value are the same for so and \$ We have

$$g = f + \mu \phi$$
,

$$\frac{\partial g}{\partial x_i} = 2(x_i - \alpha) + \mu b_i = 0 \qquad i = 1, 2, 2. \tag{3}$$

From the four equations 1), 2), we flad

$$\mu \simeq 2 \frac{a_1b_1 + a_2b_3 + a_3b_3 + b_0}{b_1^2 + b_2^2 + b_3^2}$$

Hence at this point
$$z = \xi$$
,
 $w = \frac{(a_1b_1 + a_2b_1 + a_3b_4 + b_3)^2}{b_1^2 + b_2^2 + b_3^2}$ (6)

To ascertain if \$ is a point of minimum, consider the value of d'ur at this point. We have $dq = \Sigma \{2(x_1 - a_1) + \mu b_1\} dx_0$ c = 1, 2, 3.

$$d^2\sigma \approx 2 \sum dx^2$$

As this is positive, & is a point of minimum. Thus the least distance \$6 from \$6 to o is determined by 3) We get

$$s_0 = \frac{a_1b_1 + a_2b_2 + a_3b_3 + b_0}{\sqrt{b_1^2 + b_2^2 + b_3^2 + b_3^2}}$$

CHAPTER XII

INTEGRATION

Geometric Orientation

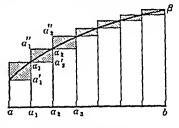

487. 1. As the reader is probably aware, the integral calculus arose from attempts to find the length of curves, the area of surfaces, and the volume of solids.

Before taking up the general theory of integration, let us see how the problem of finding the area of a simple figure leads to an integral.

2. In the interval $\mathfrak{A} = (a, b)$ let y = f(x) be an increasing continuous function whose graph Γ is given in the adjoining figure.

We seek the area A of the figure $ab\alpha\beta = F$. The upper boundary of F is the curve Γ .

To find the area of a circle in elementary geometry, we form a sequence of inscribed and circumscribed polygons. Each inscribed polygon is contained in the circle;

cach circumscribed polygon contains the circle. We say the area of the circle is therefore less than any of the outer polygons, and greater than any of the inner polygons. We then show that the areas of these two systems of polygons have a common limit as the number of the sides increases indefinitely. This limit is then, by definition, the area of the circle.

We shall adopt a similar procedure here, reserving for later a more thorough discussion in connection with other fundamental geometric notions.

Let us divide (a, b) into n equal intervals by introducing the points a_1, a_2, a_3, \cdots

Over each interval (a, a, i) we have two rectangles

$$r_m = a_m a_{m+1} a_m a'_{m+1}, \qquad a_m = f(a_m),$$

and

$$R_m = \sigma_m a_{m+1} a_m^{tt} a_{m+1}$$
 Let
$$s_m = r_m + r_m + \dots + r_{m+1}$$

$$S_{i} = R_{i} + R_{i} + \dots + R_{i-1}$$

Then S_a contains F, while ϵ_a is contained in F. Let us now divide each of the intervals

$$(a, a, b, (a_1, a_2), (a_2, b))$$

into two equal parts We get two new sums s_m and S_m . In this way we may continue without end Let us now give n the values 1, 2, 4.

We get two limited univariant sequences

$$s_1 < s_2 < s_4 < s_6 < S_1$$
,
 $S_1 > S_2 > S_4 > S_6 > s_1$

Each sequence has a limit by 109 These limits are, moreover, the same For $S_s - s_s$ is obviously the area of the shaded region in the figure

Hence

$$S_{\bullet} - s_{\bullet} = (\beta - a) \frac{b - a}{n}$$

Evidently

$$\lim \left(S_a - s_a \right) = 0$$

Hence

$$\lim S_{\mathbf{a}} = \lim s_{\mathbf{a}}$$

As in the case of the circle, the common limit is, by definition, the area of ${\cal F}$

3 Now

$$r_{n} = \frac{b-a}{n} f(a_{n})$$

Hence

$$s_a = \frac{b-a}{a} \{ f(a) + f(a_1) + + f(a_{n-1}) \};$$
 (1)

and therefore, setting for uniformity, $a_0 = a$,

$$A = \lim_{n \to \infty} \sum_{m=0}^{n-1} f(a_m) \frac{b-a}{n}$$
 (2)

But as the reader knows, the expression on the right of 2) is the integral $\int_{a}^{b} f(x) dx.$

Let us find the limit A of 487, 2) for the function 488. Example.

Set

$$f(x)=c^x. \qquad c>0.$$

$$\frac{b-a}{n}=\delta;$$

then

$$a_m = a + m\delta$$
, $m = 0, 1, \dots n-1$.

and

$$f(a_m) = c^{a+m\delta} = c^a c^{m\delta}.$$

Hence

$$s_n = \delta \cdot c^a \{1 + c^\delta + c^{2\delta} + \dots + c^{(n-1)\delta}\}$$

$$= \delta \cdot c^{a} \frac{1 - c^{ab}}{1 - c^{b}} = (c^{b} - c^{a}) \frac{\delta}{c^{b} - 1}.$$
 (1)

Now

$$\lim_{\delta \to 0} \delta = 0.$$

Also, by 311.

$$\lim_{\delta = 0} \frac{\delta}{c^{\delta} - 1} = \frac{1}{\log c}.$$

From 1), 2) we have

$$A = \lim s_n = \frac{c^b - c^a}{\log c}.$$

Analytical Definition of an Integral

489. 1. Let f(x) be a limited function, defined over the interval $\mathfrak{A} = (a, b), a < b$. Let us divide $\mathfrak A$ into n sub-intervals $a = a_1 a_2 a_3 a_4$

$$\delta_m = (a_{m-1}a_m), \qquad m = 1, 2, \dots n$$

by interpolating at pleasure the points

$$a_1, a_2, \cdots a_{n-1}.$$
 (1)

For uniformity of notation, we set

$$a = a_0$$
, $b = a_0$

This set of points 1) produces a division of M, which we

$$D = D(a_1, a_m, a_{m-1})$$

Since no confusion can arise, let δ_n denote also the length of the interval δ_n . The greatest of these lengths we call the norm of D and denote it by δ

In each δ_m let us take a point ξ_m at pleasure, and build the sum

$$J_i = \sum_{n=1}^{\infty} f(\xi_n)(a_n - a_{n-1}) = \sum_n f(\xi_n)\delta_n$$
 (2)

In passing, let us note that the sums S_n s_n of 487 are special cases of 2)

cases of 2)

Let now $\delta = 0$ If J_0 converges to a limit J, which is independent of the choice of the points $a_m \in B_m$, we write

$$J = \lim_{n \to \infty} \sum_{i=1}^{n} f(x_i) \delta_n = \int_{-\infty}^{\infty} f(x_i) dx$$

We say f(z) is integrable from a to b and call J the integral of f(z) from a to b f(z) is called the integrand, a, b are respectively the lower and upper limits of integration. We also write

$$J = \int f dx$$

The symbol f is a long S, the first letter of the word sum

2 To fix the ideas, we have taken a < b Then in 21, the numbers

$$\delta_{-} \approx (a_{-} \rightarrow a_{-})$$

are positive

If we had taken a > b, the δ s would be all negative Evidently whether a is greater or less than b, if

exists, then

$$\int_{x}^{x} f(x)dx$$
 (3)

$$\int_{0}^{x} f(x)dx$$
 (4)

exists and 3), 4) have the same numerical value, but are of opposite sign Without loss of generality, we may therefore, in our discussion, take a < b so that the δ 's are > 0.

3. Obviously the symbol

$$\int_a^b f(x) dx$$

has no sense when a = b. In this case we shall assign to it the value 0.

4. Let f(x) be integrable in $\mathfrak{A} = (a, b)$, and

Then
$$\left| \int_a^b f dx \right| \leq M.$$

$$\left| \int_a^b f dx \right| \leq M(b-a).$$
For,
$$-M \leq f(\xi_m) \leq M.$$
Hence
$$- \sum M \delta_m \leq J_\delta \leq \sum M \delta_m,$$
or,

 $-M(b-a) \leq J_s \leq M(b-a)$.

Passing to the limit, $\delta = 0$,

$$-M(b-a) \leq \int_a^b f dx \leq M(b-a),$$

which is 5).

Upper and Lower Integrals

490. Before deducing criteria for the integrability of f(x), we define upper and lower integrals.

Let

$$M_{\kappa} = \operatorname{Max} f(x), \qquad m_{\kappa} = \operatorname{Min} f(x), \qquad \text{in } \delta_{\kappa}.$$
 $\overline{S}_{D} = \sum M_{\kappa} \delta_{\kappa}, \qquad \underline{S}_{D} = \sum m_{\kappa} \delta_{\kappa}.$

We shall show immediately that the limits

$$\overline{S} = \lim_{\delta=0} \overline{S}_D, \qquad \underline{S} = \lim_{\delta=0} \underline{S}_D$$

exist and are finite. They are called respectively the upper and lower integrals of f(x) for the interval \mathfrak{A} , and are denoted by

$$\int_{\mathfrak{A}} f dx$$
, $\int_{\mathfrak{A}} f dx$.

OF

491 If f(x) is limited in U, the upper and lower integrals exist and are finite

Let us consider the upper integral similar reasoning is applicable to the lower integral

Corresponding to each division D there is a S_D . Let us by off these values on an axis We get a limited point aggregate

For, since f(x) is limited there exists a number M>0, such that

Hence $-\sum M \delta_{\epsilon} \leq \sum M \delta_{\epsilon} \leq \sum M \delta_{\epsilon},$

$$-M(b-a) < S_0 < M(b-a)$$

Hence, the Sa are hunted

Let
$$\bar{S}_a = \text{Vin } \bar{S}_m$$

We show now that

$$\overline{\mathcal{S}}_{\mathfrak{o}} = \lim \overline{\mathcal{S}}_{\mathfrak{o}}$$

that is, for each $\epsilon > 0$ there exists a δ_0 such that

$$\bar{S}_{p} - S_{a} < \varepsilon$$
 (1

for any division D of norm $\delta \leq \delta_0$

Since S_0 is a minimum there exists a division Δ of $\mathfrak A$ of norm n such that

$$\overline{S}_0 \le S_0 < S_0 + \frac{\epsilon}{2} \tag{2}$$

Let $\eta_1 \ \eta_2$, η_s be the intervals of Δ Let

δ δ, δ,

be the intervals of D lying wholly in $\eta := 1 2 \quad \nu$, let

 δ_i δ_b

be the other intervals of D

We take now δ_0 so small that

$$\sum \delta_{i}' < \frac{\epsilon}{4M}, \qquad \sum_{i} \left(\eta_{i} - \sum_{\kappa} \delta_{i\kappa} \right) < \frac{\epsilon}{4M}$$
 (3)

for all $\delta < \delta_0$. This is evidently possible, since Δ has only ν intervals, ν being fixed.

Let

$$M_{\iota\kappa} = \operatorname{Max} f$$
, in $\delta_{\iota\kappa}$,

$$M'_{i} = \operatorname{Max} f_{i}$$
, in δ'_{i} .

Then

$$\bar{S}_{D} = \sum M_{i\kappa} \delta_{ir} + \sum M_{i}' \delta_{i}'$$

$$\leq \sum M_{i} \delta_{i\kappa} + M \sum \delta_{i}'$$

$$\leq \bar{S}_{\Delta} - \bar{S}_{\Delta} + \sum M_{i} \delta_{i\kappa} + M \sum \delta_{i}'$$

$$\leq \bar{S}_{\Delta} + M \sum \delta_{i}' - (\sum M_{i} \eta_{i} - \sum M_{i} \delta_{i\kappa})$$

$$\leq \bar{S}_{\Delta} + M \sum \delta_{i}' + M(\sum \eta_{i} - \sum \delta_{i\kappa})$$

$$< \bar{S}_{\Delta} + \frac{\epsilon}{2}, \text{ by 3}.$$
(4)

Hence, from 2), 4),

$$\bar{S}_0 \leq \bar{S}_D < \bar{S}_\Delta + \frac{\epsilon}{2} < \bar{S}_0 + \epsilon;$$

or,

$$\overline{S}_D - \overline{S}_0 < \epsilon, \qquad \delta < \delta_0.$$
 Q. E. D

492. Ex. 1.

$$\mathfrak{A} = (0, 1).$$

$$f(x) = 1$$
 for rational points in \mathfrak{A} ,

= 0 for irrational points in A.

Then

$$\vec{S}_D = 1, \quad \underline{S}_D = 0.$$

$$\overline{S} = 1, \qquad \underline{S} = 0.$$

Ex. 2.

 $\Xi = (-R, R)$

Let f(x) he on the circumference of the circle for rational x, while it has on the edge of the inscribed square for

(1

(2

irrational &

 $\int_{\mathcal{R}} f dx = \frac{1}{2} * R^4 \text{ area of sense order},$ $\int_{\mathcal{R}} f dx = P^4 \text{ area of half the inscribed square.}$

Criteria for Integrability

493 For the limited function f(x) to be integrable in the interval I it is necessary and sufficient that

 $\int_{\mathbb{R}} f dx = \int_{\mathbb{R}} f dx$

It is sufficient For, let D be any division of norm &.
Then

 $M_{\epsilon} \geq f(\xi_{\epsilon}) \geq m_{\epsilon}$

 $M_*\delta_* \geq f(\xi_*)\delta_* \geq m_*\delta_*$ Summing, we get

 $\widetilde{S}_{\delta} \geq J_{4} \geq \underline{S}_{\delta}$ By hypothesis,

 $\lim \overline{S}_b = \lim \underline{S}_b = L$, say

Hence $\lim J_{x} = L$

It is necessary For, since the integral Jexists.

to it section. A soil sinch rue michigin a call

 $\epsilon > 0$, $\delta_0 > 0$, $|J - \Sigma f(\xi_*)\delta| < \frac{\epsilon}{4}$

for any division D of norm $\delta < \delta_0$ Let η_x be any other point in the subinterval δ_x belonging to the division D just mentioned

We have also, as m. 1),

$$|J-\Sigma f(\eta_s)\delta_s| < \frac{\epsilon}{4}$$

Subtracting 1), 2), we have

$$|\Sigma f(\xi_{\kappa})\delta_{\kappa} - \Sigma f(\eta_{\kappa})\delta_{\kappa}| < \frac{\epsilon}{2}, \tag{3}$$

for any division of norm $\delta < \delta_0$.

On the other hand, in each δ_{κ} there are points ξ_{κ} , η_{κ} , such that

$$M_{\kappa} < f(\xi_{\kappa}) + \frac{\epsilon}{4(b-a)},$$

$$m_{\kappa} > f(\eta_{\kappa}) - \frac{\epsilon}{4(b-a)}$$

Multiplying these inequalities by δ_{κ} and adding, we have

$$\overline{S}_D = \Sigma M_{\kappa} \delta_{\kappa} < \Sigma f(\xi_{\kappa}) \delta_{\kappa} + \frac{\epsilon}{4},$$

$$\underline{S}_0 = \sum m_{\kappa} \delta_{\kappa} > \sum f(\eta_{\kappa}) \delta_{\kappa} - \frac{\epsilon}{4}$$

Hence

$$\overline{S}_{D} - \underline{S}_{D} < \Sigma f(\xi_{\kappa}) \delta_{\kappa} - \Sigma f(\eta_{\kappa}) \delta_{\kappa} + \frac{\epsilon}{9}$$

This gives, using 3),

$$\overline{S}_D - \underline{S}_D < \epsilon$$
.

Hence

$$\overline{S} - \underline{S} < \epsilon$$
; hence $\overline{S} = \underline{S}$.

494. We can state the theorem of 493 a little differently by introducing the following definitions. The difference between the maximum and minimum of a function f(x) in an interval \mathfrak{A} , is called the oscillation of f in \mathfrak{A} . It cannot ever be negative. Let D be any division of \mathfrak{A} into subintervals δ_x , of length δ_x . Let ω_x be the oscillation of f in δ_x . The sum

$$\sum \omega_{n} \delta_{n} = \Omega_{D} f = \Omega f$$

is called the oscillatory sum of f for the division D.

We have

$$\Omega_{D}f = \sum (M_{\kappa} - m_{\kappa}) \, \delta_{\kappa} = \sum M_{\kappa} \delta_{\kappa} - \sum m_{\kappa} \delta_{\kappa}
= \overline{S}_{D} - \underline{S}_{D}.$$
(1)

495 In order that the limited function f(x) be integrable in X it is necessary and sufficient that

$$\lim_{t\to 0} \Omega f = 0$$

For, by 494 1)

or when and only when

$$\Omega f = \delta_{\rho} - \delta_{\rho}$$

By 493 f(x) is integrable when and only when

 $\lim_{b \to \infty} S_b = \lim_{b \to \infty} \underline{S}_{b},$

 $\lim_{b \to \infty} (\delta_b - \underline{S}_b) = 0,$

which is 1) 496 If

496 If f(x) is integrable in A it is integrable in any partial interval B of A

Let

$$\mathfrak{A} = (a \ b) \ \mathfrak{B} = (a, \beta) \ a \ a \ b$$

Since $\lim_{\delta \to 0} \sum_{s} \omega \, \delta_{s} = 0 \tag{1}$

for any system of divisions whose norm $\delta=0$, let us consider only such divisions involving the points α,β . Let D_1 be the division of $\mathfrak B$ produced by D. Then

 $0 \le \sum_{p} \omega_{r} \delta_{r} \le \sum_{p} \omega_{r} \delta_{s} \tag{2}$

since the first sum contains only a part of the intervals δ_{ϵ} and ω_{ϵ} is $\lessgtr 0$

Passing to the limit in 2) we have by 1),

$$\lim_{t\to 0} \sum_{p} \omega \, \delta_{n} = 0$$

Hence f(x) is integrable in \mathfrak{B}

497 In order that the limited function f(x) be integrable in \P it is necessary and sufficient that for each $\epsilon > 0$ there exists at least one division D for which $\Omega_0 f < \epsilon$

That this condition is necessary follows at once from 495

It is sufficient. For, by 494, for the division D

$$\bar{S}_D - \underline{S}_D < \epsilon$$
. \underline{S}_D \bar{S}_D

But then, as the figure shows,

$$\widehat{S}_0 - \underline{S}_0 < \epsilon$$
;

or, by 491,

$$\int_{\mathfrak{A}} f dx - \int_{\mathfrak{A}} f dx < \epsilon.$$

But then, by 87, 5,

$$\int_{\mathfrak{A}} f dx = \int_{\mathfrak{A}} f dx.$$

Therefore, by 493, f(x) is integrable.

498. In order that the limited function f(x) be integrable in \mathfrak{A} , it is necessary and sufficient that for any pair of positive numbers ω , σ , there exists a division D of \mathfrak{A} , such that the sum of the subintervals* of D in which the oscillation of f(x) is $> \omega$, is $< \sigma$.

It is necessary. For, by 497, there exists a division D for which $\Omega_D f$ is as small as v. 9 please, and therefore

$$\Omega_D f = \sum \omega_s \delta_s < \omega \sigma. \tag{1}$$

Let the intervals of D for which the oscillation of f is $\ge \omega$, be denoted by D_s , those for which the oscillation is $< \omega$, by d_s .

Then

$$\Sigma \omega_s \delta_s = \Sigma \omega_s D_s + \Sigma \omega_s d_s = \Sigma \omega_s D_s = \omega \Sigma D_s.$$

This, with 1), gives

$$\omega \sigma > \omega \Sigma D_{\star}$$
.

Hence

$$\Sigma D_{-} < \sigma$$
.

It is sufficient. For, having taken $\epsilon > 0$ small at pleasure, take

$$\sigma = \frac{\epsilon}{2(M-m)}, \quad \omega = \frac{\epsilon}{2(b-a)},$$
 (2)

where

$$M = \operatorname{Max} f, \ m = \operatorname{Min} f, \quad \text{in } \mathfrak{A}.$$

[·] For brevity, instead of sum of the lengths of the subintervals.

Then, by hypothesis, there exists a division D for which

$$\Sigma D. < \sigma$$

This, with 2), gives

$$\begin{split} &\Omega_D f = \Sigma \omega_e D_e + \Sigma \omega_e \hat{d}_e \\ &< (M-m) \Sigma D_e + \omega \Sigma \hat{d}_e \\ &< (M-m) \sigma + \omega (b-a) = \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon. \end{split}$$

There is, therefore, at least one division D for which

$$\Omega_{h}f < \epsilon$$

Then, by 497, f is integrable in %

Classes of Limited Integrable Functions

483 If f(x) is continuous in the interval \Re , it is uniformly continuous that, it is uniformly continuous thence, by 85%, we can divide \Re into subintervals of length $\delta > 0$, such that the oscillation of f in each interval is $< \omega$, an arbitrarily small positive number. There is thus no subinterval in which the oscillation $\leq \omega$.

Therefore, by 498, f is integrable in M

500 If f(x) is limited in the interval $A = \{a \mid b\}$ and has only a finite number of points of discontinuity a_i , $a_n = a_n$ it is integrable in A

Let ω σ be any pair of positive numbers On either side of the points a_s mark the points a_s' , a_s'' , $\kappa = 1, 2$,

s, as in the figure, but such that the total length of these little intervals is $<\sigma$.

Since f is continuous in (a, a_1') , we can divide it into subintervals such that the oscillation of f in each of them is $<\omega$

The same is true of the intervals (a', a'), (a', a'),

But this set of cubintervals in A gives a division of A for which the sum of the intervals in which the oscillation is $\ge \omega$ is $< \sigma$. Hence, by 498, f is integrable in A

- 501. 1. In 263 we saw there were point aggregates having derivatives (not 0 of eourse) of every order. This leads us to divide point aggregates into two classes or species. The first embraces all point aggregates whose derivatives after some order vanish. The second embraces aggregates having non-zero derivatives of every order.
- 2. Let f(x) be limited in the interval $\mathfrak A$. If its points of discontinuity form an aggregate Δ of the first species, f is integrable in $\mathfrak A$.

We note that the aggregate Δ in 500 is of order 0.

We prove the above theorem by complete induction. Let us assume therefore that f is integrable when Δ is of order n-1, and show f is integrable when Δ is of order n.

Since Δ is of order n, $\Delta^{(n)}$ embraces only a finite number of points, by 265. Call these

$$a_1, a_2, \cdots a_s$$

As in 500, we can inclose them in little intervals $(a_1^i, a_1^{i^i})$... The points of discontinuity in the intervals

$$\mathfrak{A}_1 = (a, a_1'), \ \mathfrak{A}_2 = (a_1'', a_2'), \ \cdots$$

form an aggregate of order n-1. Hence, by hypothesis, f(x) is integrable in \mathfrak{A}_1 , \mathfrak{A}_2 , ...

Then each interval \mathfrak{A}_{κ} can be divided into subintervals by 498, so that the sum of the intervals in which the oscillation of f is $>\omega$ is as small as we please. As in 500, the totality of these little subintervals furnishes a division of \mathfrak{A} for which the sum of the intervals in which the oscillation is $>\omega$ is $<\sigma$, an arbitrarily small number. Then, by 498, f(x) is integrable in \mathfrak{A} .

502. Let f(x) be limited and monotone in \mathfrak{A} ; then f(x) is integrable in \mathfrak{A} .

If f(x) is constant, the theorem is obvious. We may therefore exclude this case. We show that for each $\epsilon > 0$ there exists a division D for which $\Omega_{B}f < \epsilon$.

Then, by 497, f is integrable.

To fix the ideas, suppose f(x) is increasing Let us divide $\mathfrak A$ into equal intervals of length

$$\delta < \frac{\epsilon}{f(b) - f(a)}$$

Then

$$\begin{aligned} & \Omega_b f = \delta \left[\left\{ f(a_1) - f(a) \right\} + \left\{ f(a_2) - f(a_1) \right\} + \\ & = \delta \left\{ f(b) - f(a) \right\} \end{aligned}$$

<ε, by 1)
503. Example

For let Let $f(z) = \frac{1}{2^{n-1}} < z > \frac{1}{2^n}$ f(z) = 0 f(z) = 0 f(z) = 0

Here f is monotone increasing and him ted in the interval $\mathfrak{A}=\{0\ 1\}$. It is therefore integrable in \mathfrak{A} . It has an infinite number of points of discontinuity, via the points

Properties of Integrable Functions

504 If $f_1(x)$, $f_n(x)$ are limited and integrable in the interval $\mathfrak A$

Then $F(x) = c_i f_i + + c_i f_e$ es constants,

is integrable in II. and

 $\int_{\mathbb{R}} F dz = e_i \int_{\mathbb{R}} f_i dx + + e_i \int_{\mathbb{R}} f_i dx \qquad (1$ $\Sigma F(\xi_i) \delta_i = e_i \Sigma f_i(\xi_i) \delta_i + + e_i \Sigma f_i(\xi_i) \delta_i$

Passing to the limit we get 1)

505 If f(x), g(x) are limited and integrable in II,

$$h(x) = f(x)g(x)$$

18 integrable in A

1. Suppose first that f(x), g(x) are >0 and < M in \mathfrak{A} . Let D be any division of \mathfrak{A} . Let δ_{κ} be one of the subintervals. Let

$$O_h$$
, O_p , O_g

be the oscillations of h(x), f(x), g(x) in δ_{κ} .

Let

F, f,

G. g.

be the maximum and minimum of f(x) and g(x) respectively in δ_r .

Then

$$O_h \gtrsim FG - fg = F(G - g) + g(F - f)$$
$$= FO_o + gO_f < MO_f + MO_g.$$

Hence

$$\Omega_{D}h \leq M\Sigma O_{f}\delta_{\kappa} + M\Sigma O_{g}\delta_{\kappa} = M\Omega_{D}f + M\Omega_{D}g.$$

Since for $\delta = 0$,

$$\lim \Omega_D f = 0, \lim \Omega_D g = 0,$$

we have

$$\lim \Omega_D h = 0.$$

Hence, by 495, h(x) is integrable in \mathfrak{A} .

2. If f(x), g(x) are not positive, we can add the positive numbers α , β to them so that

$$f_1(x) = f(x) + \alpha$$
, $g_1(x) = g(x) + \beta$

are positive, and by 504, integrable.

Then

$$f_1(x)g_1(x) = f(x)g(x) + \alpha g(x) + \beta f(x) + \alpha \beta.$$

Hence

$$f(x)g(x) = f_1(x)g_1(x) - \alpha g(x) - \beta f(x) - \alpha \beta.$$
 (1)

Each term on the right side of 1) is integrable by what precedes Hence f(x)g(x) is. 506 In the interval M let

where A B are both positive or both negative numbers. If f(x) is integrable in $\mathfrak A$ so is

$$g(x) = \frac{1}{f(x)}$$

To fix the ideas, suppose A B are positive Using the notation of 505.

 $O_s = \frac{1}{f} - \frac{1}{F} = \frac{F - f}{fF} < \frac{F - f}{A^2} = \frac{O_s}{A^2}$

Hence

$$0 \le \Omega_1 g < \frac{1}{43} \Omega_b f$$
 (1)

As f(x) is integrable

$$\lim_{\longrightarrow} \Omega_p f = 0$$

Hence g(x) is also integrable, by 1) and 495

50% If f(x) is limited and integrable in A, so is

$$g(x) = |f(x)|$$

For, using the notation of 505

obviously Therefore

$$0 \le 0$$

$$0 < \Omega_{n}q < \Omega_{n}f$$

As
$$\lim \Omega_{\alpha} f = 0$$
,

g(x) is integrable by 495

508 In 501 503 we have met with integrable functions which have an infinite number of discontinuities in M. There is, how ever, a limit to the discontinuity of a function beyond which it ceases to be integrable, viz

If the limited function f(x) is integrable in the interval \mathfrak{A} , there are an infinity of points in any partial interval B of A, at which f is continuous.

Let $\omega_1 > \omega_2 > \cdots$ be positive and $\doteq 0$. By 498 there exists a division such that the sum of the intervals in which the oscillation of f is $\geq \omega_1$ is $< \sigma$. Thus, if σ be taken less than \mathfrak{B} , there is at least one subinterval within B, call it B1, in which the oscillation is $<\omega_1$. Similarly, there is an interval \mathfrak{B}_2 within \mathfrak{B}_1 , in which the oscillation of f is $<\omega_2$. Continuing this way, we can get a sequence of intervals

B, B1, B2, ... (1

each contained within the preceding, whose lengths = 0. Then, by 127, 2, the sequence 1) defines a point c within \mathfrak{B} , such that for every point x in D(c),

$$|f(x)-f(c)|<\omega.$$
 w arbitrarily small.

Thus \mathfrak{B} contains at least one point c, at which f(x) is continuous. It therefore contains an infinity of such points.

Functions with Limited Variation

509. An important class of limited integrable functions is formed by functions with limited variation, which we now consider.

Let f(x) be defined over the interval $\mathfrak{A} = (a, b)$.

Let D be a division of \mathfrak{A} of norm δ ; let $\delta_1, \delta_2, \dots$ be the subintervals of A corresponding to this division.

Let ω_x denote the oscillation of f(x) in δ_x . Let us form the sum

$$\omega_D = \Sigma \omega_{\kappa}.$$

$$\tilde{\omega} = \text{Mov } \omega$$

If $\tilde{\omega} = \operatorname{Max} \omega_n$

is finite for all possible divisions D, we say f(x) is a function with limited variation, or that f(x) has a limited variation in \mathfrak{A} .

We call $\tilde{\omega}$ the variation of f(x) in \mathfrak{A} . If $\tilde{\omega}$ is infinite, we say f(x) has unlimited variation in A. If f(x) is unlimited in A, it cannot be a function with limited variation in M.

510 Let D = (a,a,) be a division of I Let us form a new division A by interpolating a point a between a _n a.

I hen & falls into two intervals &. &" in A

be the maximum of f in δ_i , δ'_i , δ''_i ,

be the minimum of f in these intervals Then the term

 $\omega_i = M_i - m_i$ in we is replaced by

n

$$\omega'_i + \omega''_i = (M'_i - m'_i) + (M''_i - m''_i)$$

in a. Now at least one of the M', M' equals M,, and at least one of the m', m' equals m. To fix the ideas, let

Then

$$M' = M \quad m'' = m,$$

$$\omega_1 - \omega_2 = (\omega' + \omega'') - \omega = M'' - m' \equiv 0$$

511 1 Let f(x) be a limited monotone function in A It has limited variation in A

To fix the ideas, let it be monotone increasing Then

$$\omega_0 = \{f(a_1) - f(a)\} + \{f(a_1) - f(a_1)\} + \{f(b) - f(a_{s-1})\} \\
= f(b) - f(a)$$

Thus, whatever division D is employed, we has the same value Hence

 $\tilde{\omega} = f(b) - f(a)$

2 Tet

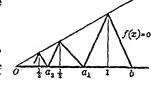

Let f(x) be monotone and limited in each interval A. Then f has limited variation in A

For, we get the maximum value of we when D embraces all the end points of the intervals M. In fact, let D be a division which does not include one of these end points, say a which lies in the interval δ_i . Let Δ be a division formed by adding α to D. Then, by 510, 1), $\omega_{\lambda} \subseteq \omega_{D}$.

If, on the other hand, D is a division including all the end points of \mathfrak{A}_1 , \mathfrak{A}_2 , ... we cannot increase ω_D by adding other points to D, as we saw in 1. Thus the variation of f(x) in \mathfrak{A} is the sum of the variations in each \mathfrak{A}_x . As these latter are finite by 1, f is of limited variation in \mathfrak{A}_x .

512. 1. It is easy to construct functions having an infinite number of oscillations in A, which are of limited or unlimited variation.

Let b>1, and in $\mathfrak{A}=(0, b)$ take the aggregate $1, \frac{1}{2}, \frac{1}{2}, \frac{1}{4}, \dots$

Let the line *OL* make the angle 45° with the x-axis. Between each pair of points

 $\frac{1}{m}$, $\frac{1}{m+1}$

take a point a_m .

Let f(x) have the graph formed of the heavy lines in the figure. Let

$$D = \left(\frac{1}{n}, \ a_{n-1}, \ \frac{1}{n-1}, \ \cdots \ a_1, \ 1\right)$$

Then

$$\omega_D = 2\left(1 + \frac{1}{2} + \frac{1}{3} + \dots + \frac{1}{n}\right).$$

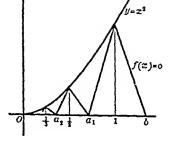

As we shall see later, the limit of the expression on the right is infinite.

Hence f(x) is of unlimited variation.

2. To form a function having limited variation, take the parabola,

$$y=x^2$$

instead of the right line OL in the last example.

Then

$$\omega_{\beta} = 2\left(1 + \frac{1}{2^2} + \frac{1}{3^2} + + \frac{1}{n^2}\right)$$

But as we shall see, the hmit of the right side is here finite. Hence f(x) is of limited variation

3 Similar considerations show that

$$y=x\sin\frac{1}{z}, x\neq 0, y=0 \text{ for } x=0$$

has unlimited variation in $(0, \delta)$, while

$$y=x^2\sin\frac{1}{x}$$
, $x\neq 0$, $y=0$ for $x=0$

has limited variation in (0, 6)

513 If f(x) has limited variation in A it is integrable in &

We apply the criterion of 498 Let then, ω, σ be an arbitrary pair of positive numbers Let D be a division of norm & Let ν be the number of subintervals in which the oscillation of f(z)is > w Then, for any division whatever,

m<~.

where & is the total variation of f in M.

Let

ρ⇔~, then

v < 0

Let us take $\delta < \frac{\sigma}{2}$ Then the sum of the intervals in which the oscillation of f is \$\square \omega\cep6<\sigma <\nd\left<\rho\delta<\square

Content of Point Aggregates

514 1 Let Δ be a point aggregate lying in the interval % For example, A may be the interval I itself Or it may consist of a certain number of partial intervals of M. Or it may embrace an infinity of subintervals with or without their end points after the manner of Ex. 7, 8 in 271. Or it may consist of a mixed system of intervals and points not forming intervals.

Let us effect a division D of A into subintervals

$$\delta_1, \ \delta_2, \ \cdots \ \delta_n$$

as heretofore.

Let

$$\delta_1', \delta_2', \cdots$$
 (1

be those intervals of D in which points of Δ fall. Let

$$\delta_1^{\prime\prime}, \ \delta_2^{\prime\prime}, \ \cdots$$
 (2)

be those intervals of D, all of whose points lie in Δ .

Then

$$\overline{\Delta} = \lim_{\delta = 0} \Sigma \delta_{\kappa}^{\prime}, \qquad \underline{\Delta} = \lim_{\delta = 0} \Sigma \delta_{\kappa}^{\prime\prime}$$

exist and are finite.

In fact, let us introduce an auxiliary function f(x) whose value is 0 in \mathfrak{A} , except at the points of Δ , where its value is 1.

Then evidently, using the notation and results of 490, 491,

$$\sum_{D} \delta_{\kappa} = \sum M_{\kappa} \delta_{\kappa} = \overline{S}_{D},$$

since $M_{\kappa} = 1$ if δ_{κ} is in 1), but is otherwise 0.

$$\sum_{D} \delta_{\kappa}^{II} = \sum m_{\kappa} \delta_{\kappa} = \underline{S}_{D},$$

since $m_{\kappa} = 1$ if δ_{κ} is in 2), but is otherwise 0.

Hence

$$\overline{\Delta} = \overline{S}, \quad \underline{\Delta} = S.$$

2. The numbers $\overline{\Delta}$, $\underline{\Delta}$ are called the upper and lower content of Δ .

When

$$\overline{\Delta} = \Delta$$
,

their common value is called the content of Δ . We denote it by

Cont
$$\Delta$$
,

or when no confusion can arise, by Δ .

The upper and lower contents may be denoted by

$$\overline{\Delta} = \overline{\operatorname{Cont}} \, \Delta, \qquad \underline{\Delta} = \underline{\operatorname{Cont}} \, \Delta.$$

A limited point aggregate having content is said to be measurable.

515 Let B be a partial aggregate of A Let E = A - B be the complementary aggregate If A and B are measurable, so is C. and

Cont
$$\mathfrak{C} = \text{Cont } \mathfrak{A} - \text{Cont } \mathfrak{D}$$
 (1

(8

For, let D be a division of norm & Let & be the frontier of H Let Mm Bn Cm Bn be the sum of the intervals of D containing points of M. B. C & respectively Let M. B. Co be the sum of the intervals which he wholly in I, B, C, respectively

Then

$$\widehat{\mathfrak{A}}_{\rho} \leq \widehat{\mathfrak{B}}_{\rho} + \widehat{\mathfrak{C}}_{\rho} \leq \widehat{\mathfrak{A}}_{\rho} + \widehat{\mathfrak{F}}_{\rho},$$
 (2)

since some of the intervals of D may contain both points of & and C, and are therefore counted twice on the middle member of 2) Similarly. Massa+Casma-Fo

Passing to the limit, $\delta = 0$, in 2), 3), we get

74 8 + C < 7.

2 > 20 + C > 31 N = N = Cont N, B = B = Cont B

Nut Hence

C=C=Cont M - Cont B,

which gives 1)

516 1 By the aid of the auxiliary function f(x) introduced in 514, 1, the criteria for integrability which we deduced in 495, 497 give at once criteria that A have a content. Thus 490 gives

In order that A have content at as necessary and sufficient that the sum of those entervals containing both points of and points not in A, converge to zero as the norm & of D converges to zero

2 From 497 we have

In order that A have content at as necessary and sufficient that for each positive number a there exists a division D of M such that the sum of the intervals in which both points of A and not of A occur, 18 < 6

EXAMPLES

517. 1. Δ = rational numbers in $\mathfrak{A} = (a, b)$.

Here

$$\overline{\Delta} = b - a, \quad \underline{\Delta} = 0.$$

2.

$$\Delta = 0, 1, \frac{1}{2}, \frac{1}{3}, \frac{3}{4}, \cdots$$

$$0 + \frac{1}{4} + \frac{1}{4}$$

Let $\epsilon > 0$ be arbitrarily small.

Let us define the division D as follows. Inclose each of the points

$$1, \frac{1}{2}, \frac{1}{3}, \cdots \frac{1}{n-1}$$

within intervals of length

$$\frac{\epsilon}{3n}$$
,

where

$$n > \frac{3}{\epsilon}$$
.

The remaining points of Δ fall in the interval

$$\left(0,\frac{1}{n}+\delta\right), \quad \delta=\frac{\epsilon}{3}$$

Then the sum of the intervals containing both points in Δ and not in Δ is $<\epsilon$. Hence, by 516, 2, Δ has a content.

As obviously

$$\Delta = 0$$

we have

Cont
$$\Delta = 0$$
.

If E is the complement of Δ in \mathfrak{A} ,

Cont
$$E = \text{Cont } \mathfrak{A} = (b - a)$$
,

by 515.

518. 1. A point aggregate of content zero is called discrete. Such an aggregate is given in 517, Ex. 2.

Every limited point aggregate of the first species is discrete.

The reasoning is perfectly analogous to that of 501.

2. Let f(x) be limited in the interval \mathfrak{A} . If the points of discontinuity of f(x) form a discrete aggregate, f(x) is integrable in \mathfrak{A} .

This follows at once from 497.

3. Let y = f(x) be univariant in \mathfrak{A} . Let

$$\left|\frac{\Delta y}{\Delta x}\right| \le M$$
, if $\Delta x \le d$.

Let Δ be a discrete aggregate in $\mathfrak A$. The image E of Δ is also discrete.

Let us effect a division of X of norm $\delta < d$

Let δ_1 , δ_2 , be the subintervals containing points of Δ Let η_1 , η_2 be the corresponding intervals on the y axis. Then, by hypothesis.

 $\eta_s \leq M\delta_s$

Thus $\Sigma_n < M\Sigma \delta$.

But Δ being discrete, we can take δ so small that the right side of 1) is $<\epsilon$

Hence E is discrete

Generalized Definition of an Integral

519 Up to the present we have supposed that the integrand f(x) is defined for all the points of the interval $\mathfrak{A} = (a,b)$ By employing the results of the last articles, we can generalize as follows

Let B be a measurable aggregate in M, and let f(x) be a limited function defined over B. Let us effect a division

 $D(a_1, a_2, \dots)$

of M of norm 8 Those intervals

 $(a_{n}, a_{n+1}), (a_{n}, a_{n+1})$ (1

(1

all of whose points lie in \mathfrak{B} , form a system which we denote by D_1 . The lengths of the intervals 1) we denote by δ_i , δ_i , while δ_i δ_i are points taken at pleasure, one in each interval of 1) Let us build the sum

$$J_1 = \sum_k f(\xi_k^i) \delta_k^i$$

If as $\delta = \emptyset$, J_s converges to one and the same value, however the divisions D and the Fs be chosen, we call this common limit the integral of f(x) over \mathfrak{B} , and denote it by

$$\int_{\mathbb{R}} f(z)dz.$$

We say in this case that f(x) is integrable with respect to B.

520. Let f(x) be a limited function defined over a limited point aggregate $\mathfrak B$ of content zero. Then f(x) is integrable over $\mathfrak B$, and

$$\int_{\mathfrak{V}} f(x) dx = 0.$$

Let

$$J_{\delta} = \sum_{D_{i}} f(\xi_{\kappa}^{\prime}) \delta_{\kappa}^{\prime}$$

have the same meaning as in 519.

Since f is limited, let

$$|f(x)| < M$$
.

Then

$$|J_{\delta}| < M \Sigma \delta_{\kappa}'$$

Since B is of content zero,

$$\lim_{\delta=0} \Sigma \delta_{\kappa}' = 0.$$

Hence

$$\lim_{\delta=0} J_{\delta} = 0,$$

which proves the theorem.

521. 1. Let f(x) be a limited integrable function defined over the measurable aggregate \mathfrak{B} . Let the interval $\mathfrak{A}=(a,b)$ contain \mathfrak{B} .

Let

$$g(x) = f(x),$$
 in \mathfrak{B} ;
= 0, for points of \mathfrak{A} not in \mathfrak{B} .

Then g(x) is integrable in (a, b), and

$$\int_{a}^{b} g(x)dx = \int_{\mathfrak{Y}} f(x)dx. \tag{1}$$

Let us effect the division D of \mathfrak{A} as in 519.

As before, let D_1 be the system of intervals lying in \mathfrak{B} . Let D_3 be the system of intervals containing no point of \mathfrak{B} . Let Δ be the system of intervals containing both points of \mathfrak{B} and points not in \mathfrak{B} .

We build now the sum

$$J_{\delta} = \sum_{\mathbf{D}} g(\boldsymbol{\xi}_{\mathbf{K}}) \delta_{\mathbf{K}}$$

with reference to the interval M.

Since

$$D = D_1 + D_2 + \Delta,$$

se have

$$J_i = \sum_{k_i} g(\xi_k) \delta_k + \sum_{k_i} g(\xi_k) \delta_k + \sum_{k} g(\xi_k) \delta_k.$$
 (2)

Since g(x) = 0 in D_2 the second sum in 2) is 0 Since

$$f(x) = g(x)$$

in
$$D_1$$
, we have now
$$J_s = \sum_{k_1} f(\xi_s) \delta_s + \sum_k g(\xi_s) \delta_s$$
 (3)

Now, by hypothesis, f is integrable in &, and

$$\lim_{\xi \to 0} \sum_{\xi} f(\xi_s) \delta_s = \int_{\mathcal{B}} f dx$$

On the other hand,

$$\lim_{n\to\infty} \sum_{\Delta} g(\xi_x) \delta_x = 0,$$

by 516 and 520

Hence, passing to the limit, $\delta \approx 0$, in 3), we have 1)

2 The reasoning in 1 gives as corollary

If f(x) is limited in B and g(x) is integrable in U, then f(x) is integrable in B. and

$$\int_{x}^{b} g(x) dx = \int_{M} f(x) dx$$

This is at once evident, on passing to the limit in 8)

3 Let f(x) be limited in A = (a b) Let ∆ be a discrete aggre gate in A Let B = A - A Let f(x) be integrable in B Then f(x) is integrable in Il. and

$$\int_{a}^{1} f dx = \int_{\mathcal{D}} f dx$$

The demonstration is similar to 1, omitting the system D,

522 1 Let f(x) be a limited integrable function with respect to the measurable aggregate B, lying in the interval X = (a, b) Let D=1a, a, a, be a division of % of norm & Let

$$(\alpha_1\beta_1)$$
, $(\alpha_2\beta_2)$,

be resulting intervals formed of one or several contiguous intervals of D, lying in B. Then

$$\int_{\mathfrak{B}} f dx = \lim_{\delta \to 0} \sum_{\kappa} \int_{a_{\kappa}}^{\beta_{\kappa}} f dx. \tag{1}$$

Let us introduce the auxiliary function g(x) of 521. Then, by 521,

 $\int_{\mathfrak{M}} f dx = \int_{a}^{b} g dx.$

Now the division D breaks $\mathfrak A$ up into the intervals

$$(a, a_1), (a_1, a_2), (a_2, a_3), \cdots (a_{n-1}, b).$$

Letting D_1 , D_2 , Δ have the same meaning as in 521, we have

$$\int_{a}^{b} g dx = \sum_{D} \int_{a_{i}}^{a_{i+1}} g dx = \sum_{D_{i}} \int_{a_{i}}^{a_{i+1}} g dx + \sum_{D_{2}} \int_{a_{i}}^{a_{i+1}} g dx + \sum_{\Delta} \int_{a_{i}}^{a_{i+1}} g dx.$$

But

$$\sum_{\mathbf{D}_{\mathbf{i}}'} \int_{a_{\mathbf{i}}}^{a_{\mathbf{i}+1}} g dx = \sum_{\mathbf{D}_{\mathbf{i}}} \int_{a_{\mathbf{i}}}^{a_{\mathbf{i}+1}} f dx = \sum_{\mathbf{D}_{\mathbf{a}}} \int_{a_{\mathbf{K}}}^{\beta_{\mathbf{K}}} f dx;$$

while

$$\sum_{D_2} \int_{a_1}^{a_1+1} g dx = 0,$$

since g = 0 in the intervals of D_2 .

Thus,

$$\int_{a}^{b} g dx = \sum \int_{a_{\epsilon}}^{\beta_{\kappa}} f dx + \sum_{\Delta} \int_{a_{\epsilon}}^{a_{\epsilon}+1} g dx.$$
 (2)

Now, if

$$|g| \leq M$$

we have, by 489, 4,

$$\left|\sum_{\Delta} \int_{a_{i}}^{a_{i+1}} g dx\right| \leq M \sum_{\Delta} (a_{i+1} - a_{i}) = M \Delta.$$

But since B is measurable,

$$\lim \Delta = 0.$$

Hence, passing to the limit in 2), we get 1).

2 The preceding reasoning gives the corollary If f(x) is limited in B and integrable in each of the intervals

$$(\alpha_s, \beta_s)$$
 and $\sum_{a_s} \int_{a_s}^{a_s} f dx$ is convergent as $b = 0$, then

This is evident on passing to the limit in 2)

 $\int_{\mathbb{R}} f dx = \lim_{k \to 0} \sum_{n} \int_{0}^{x_{n}} f dx$ 3 Let f(x) be limited in A = (a b) Let ∆ be a discrete aggre

3 Let
$$f(x)$$
 be limited in $\Re = (a \ b)$ Let Δ be a discrete agg gate in \Re Let $\Re = \Re - \Delta$. Then
$$\int_a^b f dx = \lim_{n \to \infty} \sum_a \int_a^n f dx,$$

provided the limit on the right is finite

For by 2.

 $\lim_{z \to \infty} \sum_{z} \int_{z}^{d} f dz = \int_{\mathbb{R}^{d}} f dz$ But by 521 3

But, by 521 3
$$\int_{\mathbb{R}} f dx = \int_{a}^{b} f dx$$

CHAPTER XIII

PROPER INTEGRALS

First Properties

523. In the last chapter the integrand f(x), as well as the interval of integration \mathfrak{A} , were limited. Integrals for which this is the case are called proper integrals, in contradistinction to those in which either f(x) or \mathfrak{A} is unlimited. These latter are called improper integrals.

In this chapter we consider only proper integrals. We wish to establish their more elementary properties.

In $\mathfrak{A} = (a, b)$, we shall take a < b, unless the contrary is stated. All the functions employed as integrands are supposed to be limited and integrable in \mathfrak{A} .

524. For the sake of completeness, we begin by stating the three following properties already established respectively in 489, 2; 489, 4; 504, viz.:

$$\int_{a}^{b} f(x)dx = -\int_{b}^{a} f(x)dx, \qquad a \leq b.$$
 (1)

$$\left| \int_{a}^{b} f(x) dx \right| \le M|b-a|, \quad a \le b, \tag{2}$$

|f(x)| being $\leq M$ in the interval (a, b).

$$\int_{a}^{b} \{c_{1}f_{1} + \dots + c_{s}f_{s}\} dx = c_{1} \int_{a}^{b} f_{1}dx + \dots + c_{s} \int_{a}^{b} f_{s}dx, \quad a \geq b. \quad (3$$

525. Let a, b, c, be three points in any order. Then

$$\int_{a}^{b} f dx = \int_{a}^{c} f dx + \int_{c}^{b} f dx. \tag{1}$$

Suppose first that a < c < b Since

$$\lim \Sigma f(\xi_*)\delta_{\epsilon}$$

is the same, whatever system of division D we choose, let us con sider only such divisions in which centers — The points of D which fall in (a, c), let us call D_1 , those falling in (c, b), call D_2 .

Then $\Sigma f \delta_s = \Sigma f \delta_s + \Sigma f \delta_s$ (2

Now f(x) being integrable in X is integrable in (a, c) and (c, b), by 496

Hence, passing to the limit in 2) we get 1)

The theorem is now readily established for any other order of a, b, c

526 1 In A = (a b) let

$$m \le f(x) \le M$$

Then

$$m(b-a) \le \int_{\mathbb{R}} f dx \le M(b-a),$$

For,

$$m \leq f(\xi_{\bullet}) \leq V$$

Hence

$$\sum m\delta_{\epsilon} \leq \sum f(\xi_{\epsilon})\delta_{\epsilon} \leq \sum M\delta_{\epsilon},$$

or

$$m(b-a) \leq J_4 \leq M(b-a)$$

Passing to the limit, $\delta = 0$ we get 1)

2 In \mathfrak{A} let $f(x) \leq g(x)$ Then

$$\int_{\mathbb{R}} f dx \ge \int_{\mathbb{R}} g dx \qquad (2)$$

For.

$$h(x) = f(x) - g(x) \le 0, \quad \text{in } \mathfrak{A}$$

Hence, by 1),

$$\int \lambda dz = \int f dx - \int g dz = 0,$$

which gives 2)

527. 1. We saw in 508 that, if f(x) is integrable in \mathfrak{A} , it must have points of continuity c, in any subinterval of \mathfrak{A} . This fact leads us to state the following theorem:

Let $f(x) \equiv 0$ in \mathfrak{A} . If f is continuous at c, and f(c) > 0, then

$$\int_{\mathfrak{A}} f dx > 0.$$

To fix the ideas, suppose c is an inner point. Then by 351, 2, there exists an interval (c', c'') about c, in which $f(x) > \rho > 0$.

Hence by 526,

But

which gives 1).

$$\int_{a}^{c} f dx \ge 0, \quad \int_{c}^{c} f dx \ge \rho(c'' - c') = \sigma, \quad \int_{c}^{b} f dx \ge 0.$$

$$\int_{a}^{c} f dx = \int_{a}^{c} f dx + \int_{c}^{c} f dx \ge 0.$$

2. As corollary we have:

Let
$$f(x) \equiv g(x)$$
 in \mathfrak{A} .

If at a point c of continuity of f and g,
$$\int_{\mathfrak{A}} f dx > \int_{\mathfrak{A}} g dx.$$

3. By means of the preceding inequalities, we can often estimate approximately the value of an integral with little labor, as the following examples show.

Ex. 1.
$$.5 < \int_0^{\frac{1}{2}} \frac{dx}{\sqrt{1-x^n}} < .5236, \quad n > 2.$$
 (1)

For, if $0 < x < 1$,

 $1 < \frac{1}{\sqrt{1-x^n}} < \frac{1}{\sqrt{1-x^2}}$.

Hence *

$$\int_0^{\frac{1}{2}} dx < \int_0^{\frac{1}{2}} \frac{dx}{\sqrt{1-x^2}} < \int_0^{\frac{1}{2}} \frac{dx}{\sqrt{1-x^2}} = \arcsin \frac{1}{2} = \frac{\pi}{6},$$

Ex. 2.
$$xe^{-x^2} < \int_0^x e^{-u^2} du < \arctan x, \quad x > 0.$$
 (2) For by 413, 2, $e^x = 1 + z + \frac{z^2}{2} e^{\theta z}, \quad 0 < \theta < 1.$

[•] In order to illustrate these and a few immediately following theorems we assume the elementary properties of indefinite integrals, which are treated in 536 seq.

Hence z being a constant,

n

a

$$\int_{0}^{\infty} e^{-u^{2}} du < \int_{0}^{\infty} e^{-u^{2}} du < \int_{0}^{\infty} \frac{du}{1 + u^{2}}$$

which gives 2)

528 1 Let f(x) be limited and integrable in \mathfrak{A} ; then |f(x)| is integrable in \mathfrak{A} and

$$\left|\int_{\mathbf{w}} f dz\right| \leq \int_{\mathbf{w}} |f| dz$$

In the first place, |f| is integrable by 507

On the other hand -|f(x)| < f(x) < |f(x)|

The relation 1) landwa now by 520

2 The reader should guard against the error of assuming that f(x) is necessarily integrable in \mathfrak{A} if |f(x)| is integrable in \mathfrak{A} for example let

f(x) = 1 for rational x in \mathfrak{A}

= - 1 for irrational z in A

Then

$$|f(x)|=1$$
 for every x in \mathfrak{A}

and is therefore integrable in $\mathfrak A$ But f(x) is obviously not integrable in $\mathfrak A$

529 1 In A = (a b), let

$$m \leq g(x) \leq M$$

When not zero, let f(x) be positive Then

$$m \int_{\mathbb{R}} f dz \le \int_{\mathbb{R}} f g dz \le M \int_{\mathbb{R}} f dz$$
 (2)

For multiplying 1) by f(x) we have

 $mf \leq fg \leq Mf$ We have now 2) by 526

2. In \mathfrak{A} let $f(x) \geq 0$. Let $m \leq g(x) \leq M$. At a point c of continuity of f(x), g(x), let

$$f(c) > 0$$
, $m < g(c) < M$.

Then

$$m \int_{\mathfrak{A}} f dx < \int_{\mathfrak{A}} f g dx < M \int_{\mathfrak{A}} f dx.$$

We have only to apply 527, 1 to the functions

$$(M-g)f$$
 and $(g-m)f$.

Ex. 1.
$$\arcsin x < \int_0^x \frac{dx}{\sqrt{1-x^2 \cdot 1 - \lambda x^2}} < \frac{\arcsin x}{\sqrt{1-\lambda}}, \tag{3}$$

where

$$0 < \lambda < 1, \quad 0 < x < 1.$$

For,

$$1 < \frac{1}{\sqrt{1-\lambda x^2}} < \frac{1}{\sqrt{1-\lambda}}$$

Hence

$$\int_{0}^{x} \frac{dx}{\sqrt{1-x^{2}}} < \int_{0}^{x} \frac{dx}{\sqrt{1-x^{2}}\sqrt{1-\lambda x^{2}}} < \frac{1}{\sqrt{1-\lambda}} \int_{0}^{x} \frac{dx}{\sqrt{1-x^{2}}},$$

which gives 3).

Ex. 2.
$$.333 < \int_0^1 x^2 e^{x^2} dx < .907.$$
 (4)

For, if 0 < x < 1,

$$1 < e^{x^2} < e.$$

Hence

$$\int_0^1 x^2 dx < \int_0^1 x^2 e^{x^2} dx < e \int_0^1 x^2 dx,$$

which gives 4).

530 1. Let f(x) = g(x) in \mathfrak{A} , except for the points of a discrete as gregate Δ ; then f, g being limited and integrable,

$$\int_{\mathfrak{N}} f dx = \int_{\mathfrak{N}} g dx. \tag{1}$$

For, set

$$h(x) = f(x) - g(x).$$

Then h=0, except for the points of Δ .

Let D be a division of \mathfrak{A} . Let D_1 embrace those intervals containing no points of Δ . Let D_2 embrace the other intervals of D. Then

$$\sum_{D} h(\xi) \delta_{\kappa} = \sum_{D_1} + \sum_{D_2} = \sum_{D_2}.$$

Let now $\delta = 0$ The limit of the left side is

Since A is discrete, the limit of the right side is 0 by 520 Hence

$$\int_{\mathbb{R}} h dx = 0,$$

which proves 1)

2 As a corollary we have

In the integral

$$J = \int_{\mathbb{R}} f dz$$

we may change at pleasure the value of f(x) at the points of an arbitrary discrete aggregate without changing the value of J protided the new integrand is also limited in $\mathfrak A$

First Theorem of the Mean

531 Let f(x), g(x) be lime and antegrable in $\mathbb{I} = (a, b)$ When not 0 let f(x) be positive

Then

$$\int_{a}^{b} f g dx = G \int_{a}^{b} f dx, \quad a \leq b, \quad (1)$$

where

$$G = \operatorname{Vean} g(x)$$
, in \mathfrak{A}

For, by definition, 268, 4,

where m and M are respectively the minimum and maximum of g(x) in $\mathfrak A$. Also, by 529,

$$m \int_{\mathbb{R}} f dx \le \int_{\mathbb{R}} f g dx \le M \int_{\mathbb{R}} f dx$$
 $a < b$,

which gives 1) in this case. The case of $a > \delta$ follows now at once

The above is called the fret theorem of the mean. We give now some special cases of it. 532. Let f(x) be integrable in $\mathfrak{A} = (a, b)$. Let

 $\mathfrak{M} = \operatorname{Mean} f(x), \quad in \, \mathfrak{A}.$

Then

$$\int_{a}^{b} f(x) dx = \mathfrak{M}(b-a). \qquad a \leq b.$$

Proved, by taking one of the functions in 531, equal to 1.

533. In the interval $\mathfrak{A} = (a, b)$, let f(x) be limited, integrable, and non negative. Let g(x) be continuous. Then

$$\int_{\mathfrak{A}} fg dx = g(\xi) \int_{\mathfrak{A}} f dx, \qquad a \le \xi \le b.$$
 (1)

For, by 531, setting G = Mean g(x),

$$\int_{\mathfrak{A}} fg dx = G \int_{\mathfrak{A}} f dx.$$

But g(x) being continuous, takes on every value between its extremes including end values, while x runs over \mathfrak{A} , by 357. Hence for some ξ in \mathfrak{A} ,

 $g(\xi)=G,$

which proves 1).

534. In the interval $\mathfrak{A} = (a, b)$ let f(x) be limited, integrable and non negative. Let g(x) be continuous. At some point of continuity of f(x) let

$$m < g(x) < M$$
,

where m = Min g(x), M = Max g(x), in \mathfrak{A} .

Then

$$\int_{\mathfrak{A}} f g dx = g(\xi) \int_{\mathfrak{A}} f dx. \qquad a < \xi < b.$$

For, by 527, 2,

$$m \int_{\mathfrak{A}} f dx < \int_{\mathfrak{A}} f g dx < M \int_{\mathfrak{A}} f dx.$$

Hence,

$$\int_{\Re} fg dx = G \int_{\Re} f dx, \qquad m < G < M.$$

Now g(x) being continuous takes on its minimum m at some point a, and its maximum at some point β in \mathbb{N} by 357. More over at some point ξ in the interval (a, β) g(x) must take on the value f. As g(x) has the values m and M at the end points of this interval ξ must be exclicted this interval. Hence

535 Let f(x) be continuous in $\mathfrak{A} = (a \ b)$ Then

$$\int f dx = (b-a)f(\xi) \qquad a < \xi < b$$

This is a corollary of 534 one of the functions being 1 provided f(z) is not a constant when the theorem

is obviously true

This theorem admits a simple geometric interpretation. It states that there is a point ξ $a < \xi < \delta$ such that the area of the rectangle ABC D' is the same as that of the figure ABC D' determined by the graph of f(z)

The Integral considered as a Function of its Upper Limit

536 Let f(x) be limited and integrable in $\mathbb{I} = (a, b)$ Then

$$F(x) = \int_{-x}^{x} f(x)dx \qquad a, x \in \mathbb{N}$$

is a one valued continuous function of x in A

Since f(x) is integrable in X F has one and only one value for every x

Let $|f(x)| \leq M$

We have

 $\Delta F = F(x+h) - F(x) = \int_{a}^{x+h} f(x)dx - \int_{a}^{x} f(x)dx = \int_{x}^{x+h} f(x)dx.$

Hence $|\Delta F| \leq M|b|$ by 524, 2)

Thus if we take

$$\delta < \frac{\epsilon}{M}$$

we have

$$|\Delta F| < \epsilon$$

for every h, such that x + h falls in \mathfrak{A} , and

$$|h| < \delta$$
.

Hence F(x) is continuous in \mathfrak{A} .

537. 1. Let f(x) be limited and integrable in $\mathfrak{A} = (a, b)$. Let

$$J(x) = \int_a^x f(x) dx, \qquad \alpha, x \text{ in } \mathfrak{A}.$$

If f is continuous at x,

$$\frac{dJ}{dx} = f(x). (1)$$

To fix the ideas, let

$$a \le \alpha < x < x + h \le b$$
.

Then

$$\Delta J = J(x+h) - J(x) = \int_a^{x+h} - \int_a^x = \int_x^{x+h}$$
$$= h\mathfrak{M}, \text{ by 532,}$$

where $\mathfrak{M} = \text{Mean } f(x) \text{ in } (x, x+h).$

But since f(x) is continuous at x,

$$\mathfrak{M} = f(x) + \eta, \qquad |\eta| < \epsilon,$$

for any $h < \text{some } \delta$.

Hence

$$\frac{\Delta J}{\Delta x} = f(x) + \eta,$$

Passing to the limit, we get 1).

2. As a corollary we have:

Let f(x) be limited and integrable in $\mathfrak{A} = (a, b)$. Then

$$\lim_{\lambda \to 0} \frac{1}{h} \int_{x}^{x+\lambda} f(x) dx = f(x), \qquad x \text{ in } \mathfrak{A}, \tag{2}$$

if f is continuous at the point x.

538 1 In the interval A, let f(x) be a limited integrable function Let F(x) be a one valued function whose derivative is f(x). Then

$$\int_{-\beta}^{\beta} f dx = F(\beta) - F(\alpha) \qquad \alpha, \beta \text{ in } \%.$$

For let $D = (a_1 \ a_2, \ a_n)$ be a division of the interval (a, β) . Then by the Law of the Wean,

$$F(a_1) - F(a) = f(\xi_1)\delta_1,$$

 $F(a_2) - F(a_3) = f(\xi_2)\delta_2,$ (2)

 $F(\beta) - F(a_{n-1}) = f(\xi_n) \delta_n$

Adding the equations 2), we get, since terms on the left cancel in pairs $F(\beta) - F(\alpha) = \sum_{i} f(\xi_i) \hat{\xi}_i$ (3)

Since f(x) is integrable

$$\lim_{n\to\infty} \Sigma f(\xi_n) \delta_n = \int_{-\pi}^{\pi} f dz$$

Passing therefore to the limit in 3), we get 1).

2 Example By differentiation we verify

$$D_x = \frac{x - \lambda \operatorname{arctg}(\lambda \tan x)}{1 - \lambda^2} = \frac{1}{1 + \lambda^2 \tan^3 x}$$

for (λ| ± 1 and 2 ± (2 m + 1) π/2 Hence by 538 1

$$\int_{-1}^{x} \frac{dz}{1+\lambda^{2} \tan^{2} z} = \frac{x-\lambda \arctan(x) \left(\lambda \tan x\right)}{1-\lambda^{2}} \qquad 0 < x < \frac{x}{2}, \qquad |\lambda| \neq 1$$

The integrand is not defined for x = v/2 let us therefore assign it the value 0. The integral on the left is continuous by 536. Hence

$$\int_{0}^{\pi/2} = L \lim_{m \to 1/2} \int_{0}^{\pi} = L \lim_{m \to 1/2} \frac{x - \lambda \sin tx (\lambda \tan x)}{1 - \lambda^{2}},$$

$$\int_{0}^{\pi/2} \frac{dx}{1 + \lambda^{2} \tan^{2}x} = \frac{x(1 + \lambda)}{2(1 - \lambda^{2})} = \frac{x}{2(1 + \lambda)}.$$
(4)

As we have derived this formula we have been obliged to assume $|\lambda| \neq 1$ is however valid even when $|\lambda| = 1$. For

$$\int_{0}^{\pi/2} \frac{dz}{1 + \tan^{2} z} = \int_{0}^{\pi/2} \cos^{2} z \, dz = \int_{0}^{1} z + \frac{1}{4} \sin 2 z \Big]_{0}^{\pi/2} = \frac{\pi}{4},$$

which agrees with 4) when $|\lambda| = 1$

OT

539. Criticism. A common form of demonstration of the preceding theorem is the following. Since

$$\lim_{h=0}\frac{F(x+h)-F(x)}{h}=f(x),$$

we have

$$\epsilon > 0$$
, $\delta > 0$, $\frac{F(x+h) - F(x)}{h} = f(x) + \epsilon'$, $|\epsilon'| < \epsilon$,

for $|h| < \delta$. The equations 2) of 538 are now written

$$F(a_1) - F(\alpha) = f(\alpha)h_1 + \epsilon_1 h_1,$$

$$\vdots \qquad \vdots \qquad \vdots$$

$$F(\beta) - F(a_{n-1}) = f(a_{n-1})h_n + \epsilon_n h_n.$$

Adding, we get

$$F(\beta) - F(\alpha) = \sum f(\alpha_s) h_s + \sum \epsilon_s h_s. \tag{1}$$

If ϵ is numerically the greatest of the ϵ_s ,

$$|\Sigma \epsilon_{\kappa} h_{\kappa}| \leq \epsilon \Sigma h_{\kappa} = \epsilon (\beta - \alpha), \quad \beta > \alpha.$$

It is now assumed that $\epsilon \doteq 0$ with δ . Hence passing to the limit, $\delta = 0, 1$) gives 538, 1).

The objection to this demonstration lies in the tacit assumption that the difference quotient converges uniformly to the derivative. Cf. 404. In other words, that it is possible to divide the interval (α, β) into subintervals $h_1, h_2, \dots h_n$ such that $\epsilon_1, \epsilon_2, \dots \epsilon_n$ are all $\leq \sigma$, a positive number, small at pleasure. As elementary textbooks say nothing of uniform convergence, the above reasoning is incomplete.

540. 1. Let f(x) be limited and integrable in $\mathfrak{A} = (a, b), a \geq b$. Let $u = \phi(x)$ (1

be a univariant function in $\mathfrak A$ having a continuous derivative $\phi'(x) \neq 0$. Let $\mathfrak B = (\alpha, \beta)$ be the image of $\mathfrak A$ afforded by 1). Let

$$x = \psi(u)$$

be the inverse function of \$\phi\$ Then, if \$f[\psi(u)]\psi'(u)\$ is integrable ın B.

$$\int_{a}^{b} f(x)dx = \int_{a}^{b} f[\psi(u)]\psi'(u)du \qquad (2)$$

By 358, the correspondence between the two intervals 2. 9 is nniform

Let E(u, u,) be a division of B, of norm & Let Ar, in Il correspond to Au, in B

By the Law of the Mean.

$$\Delta x_{\epsilon} = \psi'(\eta_{\epsilon}) \Delta u_{\epsilon}, \quad \eta_{\epsilon} \text{ lying in } \Delta u_{\epsilon}$$

Let E. in A correspond to 7. in B Then

$$\sum f(\xi_*)\Delta x_* = \sum f(\psi(\eta_*))\psi'(\eta_*)\Delta u_* \qquad (8)$$

Since

$$f(z), f[\psi(u)]\psi'(u)$$

are limited, and integrable by hypothesis, we have 2) by passing to the limit in 3)

2 If the conditions of 1 are not satisfied in the intervals I B. it my be possible to divide them up into subintervals, in each of which these conditions hold

541 I Let us evaluate

$$J = \int_0^1 \frac{\log{(1+x)}dx}{1+x^2}$$
 (1)

We set

$$z = \tan u = \psi(u)$$
 or $u = arr \tan x = \phi(x)$

Then %-(0 1) 20 ≈(0 x/1)

$$I = \int_0^{\pi/4} \log(1 + \tan \pi) d\pi$$

Let us make a new transformation

The conditions of 540 being again satisfied

$$J = \int_0^{\pi/4} \log \left\{ 1 + \tan \left(\frac{\pi}{4} - v \right) \right\} dv$$

But
$$\tan\left(\frac{\pi}{4} - v\right) = \frac{1 - \tan v}{1 + \tan v}.$$
Hence
$$J = \int_0^{\pi/4} \log \frac{2 \, dv}{1 + \tan v} = \log 2 \int_0^{\pi/4} dv - J,$$
or
$$2J = \log 2 \int_0^{\pi/4} dv = \frac{\pi}{4} \log 2.$$
Thus
$$J = \pi/8 \log 2.$$
 (2

2. That we should not affect a change of variable in a definite integral, without due precaution, is illustrated by the following example.

Let
$$\int_{a}^{b} f(x) dx = \int_{-1}^{1} \frac{dx}{1+x^{2}} = \left[\text{are tg} \right]_{-1}^{1} = \frac{\pi}{2}$$
 (3)

Let us change the variable, setting

$$x=\frac{1}{u}=\psi(u).$$

Then

$$\alpha = -1$$
, $b = 1$; $\alpha = -1$, $\beta = 1$.

Also

$$\int_{-1}^{1} f(\psi(u)) \psi'(u) du = -\int_{-1}^{1} \frac{du}{1 + u^{2}} = -\frac{\pi}{2}.$$
 (4)

The two integrals 3), 4) are not equal. The reason for this is that the function

$$u = \phi(x) = \frac{1}{x}$$

of 540 does not have a continuous derivative in $\mathfrak{A}=(-1,1)$. Indeed, it is not even defined throughout $\mathfrak{A}.$

542. Let $x = \psi(u)$ have a continuous derivative in $\mathfrak{B} = (\alpha, \beta)$, $\alpha \leq \beta$. Let \mathfrak{A} be the image of \mathfrak{B} . Let f(x) be limited and integrable in \mathfrak{A} , and let $f[\psi(u)]\psi'(u)$ be integrable in \mathfrak{B} . Then

$$\int_a^b f(x)dx = \int_a^\beta f[\psi(u)]\psi'(u)du. \qquad a = \psi(a), \ b = \psi(\beta). \quad (1)$$

1. Let us note first the difference between this theorem and that of 540. In 540 $\psi(u)$ is univariant, and \mathfrak{A} , \mathfrak{B} are in uniform correspondence.

In the present theorem, ψ may have any number of oscillations in \mathfrak{B} . Furthermore, the intervals \mathfrak{A} and (a, b) may not be the same.

Example Let $x=\psi(u)-\sin u$ $\mathfrak{B}=(0$ $\frac{1}{4}\pi)$. Then the image of \mathfrak{B} is the interval $\mathfrak{A}=(-1,1)$. On the other hand $a=\sin 0=0$ $b=\sin \frac{1}{4}\pi=\frac{1}{4}$. Thus $\{a,b\}=(0,1)$ is different from \mathfrak{A} . Let f(x)=x. Then

$$\int_{a}^{b} f dx = \int_{a}^{b} f(\phi u) \phi u du = \int_{a}^{a} \int_{a}^{b} u du = \frac{1}{2}$$

Thus the two integrals are equal as the theorem requires,

2 To prove the formula 1), consider

$$F(u) = \int_{\phi(u)}^{\phi(u)} f(x)dx - \int_{u}^{u} g(u)du, \quad g(u) = f[\psi(u)]\psi^{t}(u)$$

We shall show that F(u) is a constant in $\mathfrak D$ As it is 0 at a, F=0 throughout $\mathfrak D$

To this end we show F'(x) = 0, in \mathfrak{B}

Then, by 400 2
$$F(u)$$
 is a constant in $\mathfrak B$ and therefore 0 At any point u of $\mathfrak D$ we have

 $\Delta F = \int_{-\infty}^{\phi(u)+\Delta f} f(z)dz - \int_{-\infty}^{u+\Delta u} g(u)du \qquad (2)$

$$\Delta x = \int_{\phi(u)} f(x) dx - \int_{u} g(u) du \qquad \{1$$

There are two cases

1° $\psi'(u) \neq 0$ Then, by 403 $\psi(u)$ is univariant in V(u) We can thus apply 540 Hence

$$\Delta F = 0$$
, in $V(u)$,

and therefore F'=0, at u

2° $\psi'(u)=0$ Let us apply the theorem of the mean 533 to each integral in 2) Then

$$\Delta F \simeq \Phi \Delta \psi - \Psi \Delta u$$

where

$$\Phi = \operatorname{Vean} f(x) \quad \Psi = \operatorname{Vean} g(u)$$

in Δψ, Δu respectively Thus

$$\frac{\Delta F}{\Delta u} = \Phi \frac{\Delta \psi}{\Delta u} - \Psi$$

Now
$$\lim \frac{\Delta \psi}{\Delta u} = \psi'(u) = 0.$$
 Also
$$\lim \Psi = 0,$$

since $f(\psi(u))$ is limited in \mathfrak{A} , and

$$\lim_{n\to\infty}\psi'(v)=\psi'(u)=0,$$

 ψ' being continuous. Hence F'(u) = 0, also in this case.

543. Let f(x) be limited in $\mathfrak{A} = (a, b)$, $a \ge b$. Let $u = \phi(x)$ have a continuous derivative $\phi'(x) \ne 0$ in \mathfrak{A} . Let $\mathfrak{B} = (a, \beta)$ be the image of \mathfrak{A} ; $a = \phi(a)$, $\beta = \phi(b)$. Let $x = \psi(u)$ be the inverse function of ϕ . Then

 $\int_{a}^{b} f dx = \int_{a}^{\beta} f(\psi(u)) \psi'(u) du, \tag{1}$

$$\underline{\int}_{a}^{b} f dx = \underline{\int}_{a}^{\beta} f(\psi(u)) \psi'(u) du.$$
(2)

Let us prove 1); the demonstration of 2) is similar. Since ϕ is univariant, the intervals $\mathfrak A$ and $\mathfrak B$ stand in uniform correspondence by 358. To fix the ideas let ϕ be an increasing function.

Then by 381, $\psi'(u) > 0$, and continuous. Let $E = (u_1, u_2, \cdots)$ be a division of \mathfrak{B} of norm δ into subintervals Δu_{κ} , to which corresponds a division $D = (x_1, x_2, \cdots)$ of \mathfrak{A} of norm d into intervals Δx_{κ} . Let

$$L_{\epsilon} = \operatorname{Max} f(x),$$
 in Δx_{ϵ} .
$$= \operatorname{Max} f(\psi(u)), \quad \text{in } \Delta u_{\epsilon}.$$

$$M_{\epsilon} = \operatorname{Max} f(\psi(u)) \psi^{t}(u), \quad \text{in } \Delta u_{\epsilon}.$$

$$\lambda_{\epsilon} = \operatorname{Min} \psi^{t}(u), \quad \mu_{\epsilon} = \operatorname{Max} \psi^{t}(u), \quad \text{in } \Delta u_{\epsilon}.$$

$$F = \operatorname{Max} |f|, \quad \text{in } \mathfrak{A}.$$

We have to show that

$$\bar{S}_D = \Sigma L_{\kappa} \Delta x_{\kappa}, \quad \bar{S}_E = \Sigma M_{\kappa} \Delta u_{\kappa}$$

nave the same limits.

Since $\phi'(x)$ and $\psi'(u)$ are continuous, they are uniformly continuous. Hence d and δ converge to 0 simultaneously. For this reason for any $\delta \leq \operatorname{some} \delta_{2}$

$$\mu_s - \lambda_s < \frac{\epsilon}{F[\beta - \alpha]}$$
, uniformly in \mathfrak{D}

By the Law of the Mean,

$$\Delta x_s = \psi'(v_s) \Delta u_s$$
, $v_s \text{ in } \Delta u_s$

Hence
$$\Theta = \bar{S}_{z} - \bar{S}_{z} = \Sigma \{M_{z} - L_{z}\psi'(v_{z})\}\Delta u_{z}.$$

But, obviously,

$$\operatorname{Max} f \operatorname{Min} \psi' \leq \operatorname{Vax} f \psi' \leq \operatorname{Vax} f \operatorname{Max} \psi'$$

if $\max f > 0$, while the signs are reversed if it is < 0. Thus in either case M_c lies between $L_c \lambda_c$ and $L_c \mu_c$. Also, $L_c \psi'(v_c)$ has between these same bounds. Hence

$$|M_s - L_s \Psi'(v_s)| \le L_s(\mu_s - \lambda_s) < \frac{\varepsilon}{\beta - a!}$$

Hence

$$|\Theta| < \frac{\epsilon |\Sigma \Delta u_{\epsilon}|}{|\beta - u|} = \epsilon \quad \delta < \delta_0$$

544 Let $x = \psi(u)$ have a continuous derivative in $\mathfrak{B} = (a, \beta)$, $a \ge \beta$ Let ψ vanish over a discrete a jregate Δ but otherwise let it have one sign. Let $\mathfrak{A} = (a \ b)$ be the image of \mathfrak{B} , $a = \psi(a)$ $b = \psi(\beta)$. If one of the integrals

$$X = \int_{a}^{b} f dx = \int_{\mathbb{R}^{d}} U dx = \int_{\mathbb{R}^{d}} f[\psi(u)] \psi'(u) du = \int_{\mathbb{R}^{d}} \int_{\mathbb{R}^{d}}$$

exists the other does, and both are then equal

To fix the ideas let U exist By 403 the correspondence between \mathfrak{A} . \mathfrak{B} is uniform

Let us effect a division, of norm δ of \mathfrak{B} . Let the norm of the corresponding division of \mathfrak{A} be \mathfrak{I} let \mathfrak{B}_1 be those intervals containing no points of Δ while $\mathfrak{B}_2 = \mathfrak{B} - \mathfrak{B}_1$ is the complement of \mathfrak{B}_1 .

Let M, M, correspond to B, B, respectively

$$\int_{\mathfrak{B}} = \int_{\mathfrak{B}_{i}} + \int_{\mathfrak{B}_{j}}.$$

$$\int_{\mathfrak{B}} = \int_{\mathfrak{A}},$$
(1)

But, by 543,

while, since Δ is discrete,

$$\lim_{\delta=0}\,\int_{\mathfrak{B}_{\bullet}}=0.$$

Hence 1) gives

$$\begin{split} \int_{\mathfrak{B}} &= \lim_{\delta=0} \int_{\mathfrak{A}_{\mathbf{1}}} = \lim_{\eta=0} \int_{\mathfrak{A}_{\mathbf{1}}} \\ &= \int_{\mathfrak{A}}, \quad \text{by 522, 3.} \end{split}$$

A similar reasoning holds, if we assume that X exists.

Second Theorem of the Mean

545. Let f(x) be limited and integrable in $\mathfrak{A} = (a, b)$. Let g(x) be limited and monotone in \mathfrak{A} .

$$\int_{a}^{b} f g dx = g(a+0) \int_{a}^{\xi} f dx + g(b-0) \int_{\xi}^{b} f dx, \ a \le \xi \le b.$$
 (1)

Since g is limited and monotone, it is integrable in $\mathfrak A$ by 502. Hence fg is integrable, by 505.

By 277, 8,

Let

$$g(a+0)$$
, $g(b-0)$ exist.

If g(a+0)=g(b-0), the relation 1) is obviously true. We therefore assume that these limits are different.

To fix the ideas, let g(x) be monotone increasing.

We begin by effecting a division of N,

$$D(a_1, a_2 \cdots a_{n-1}),$$

of norm δ. We also set

 $a=a_0, \qquad b=a_n.$ $M_r = \operatorname{Max} f, \qquad m_r = \operatorname{Min} f,$ in the interval $\delta_r = (a_{r-1}a_r).$

Let ξ_{ϵ} be any point in δ_{ϵ}

From 2), 3) we have

$$M > f(F) > m$$
.

we have

$$M.\delta. > f(\xi_{\bullet})\delta_{\bullet} > m.\delta_{\bullet}$$

and also

..... 4150

$$M_s \delta_s \ge \int_S f(\xi_s) dx \ge m_s \delta_s$$
.

(3

$$|f(\xi_s)\delta_s - \int_{t_s} |\leq (M_s - m_s)\delta_s$$

Hence

$$f(\xi_{\epsilon})\delta_{\epsilon} = \int_{t_{\epsilon}} f dx + \sigma_{\epsilon}, \qquad (4)$$

$$|\sigma_{\epsilon}| \le (M_{\epsilon} - m_{\epsilon})\delta_{\epsilon}$$

Vultiply 4) by $g(\xi_n)$, and letting $\kappa = 1, 2, ..., n$, let us sum the n resulting equations. We get

$$\Sigma f(\xi_*)g(\xi_*)\delta_* = \Sigma g(\xi_*) \int_{\mathbb{R}} f dx + \Sigma \sigma_* g(\xi_*)$$
 (5)

Now

$$\int_{\mathbf{q}} \approx \int_{\mathbf{q}_{1}}^{\mathbf{q}} - \int_{\mathbf{q}_{2}}^{\mathbf{q}} d\mathbf{q}$$

$$= \int_{\mathbf{q}_{1}}^{\mathbf{q}} - \int_{\mathbf{q}_{2}}^{\mathbf{q}} d\mathbf{q}$$

or more briefly,

Hence letting x = 1, 2, n, we get

$$g(\xi_1)\int_0=g(\xi_1)\int_0-g(\xi_1)\int_1$$

$$g(\xi_2)\int_{t_1} = g(\xi_2)\int_{t_1} - g(\xi_2)\int_{t_1}$$

$$g(\xi_{\bullet}, 1) \int_{t_{n-1}} = g(\xi_{n-1}) \int_{t_{n-1}} -g(\xi_{\bullet-1}) \int_{t_{n-1}} g(\xi_{\bullet}) \int_{t_{n-1}} = g(\xi_{n}) \int_{t_{n-1}} g(\xi_{\bullet}) \int_{t_{n$$

Adding, we have,

$$\sum_{g(\xi_{*})} \int_{\xi_{*}} f dx = g(\xi_{*}) \int_{*}^{s} f dx + \sum_{i=1}^{n} \left\{ g(\xi_{*}) - g(\xi_{*-1}) \right\} \int_{s-1}^{s} f dx \quad (6)$$

Since g is monotone increasing,

$$G_{\kappa} = g(\xi_{\kappa}) - g(\xi_{\kappa-1}) \equiv 0.$$

Let \mathfrak{M} be the maximum of the integral $\int_x^b f dx$, and m its minimum as x ranges over \mathfrak{A} . Then

$$G_{\mathbf{k}}\mathfrak{m} \leq \Big\{g(\xi_{\mathbf{k}}) - g(\xi_{\mathbf{k}-\mathbf{1}})\Big\} \int_{\mathbf{k}-\mathbf{1}} \leq G_{\mathbf{k}}\mathfrak{M},$$

and adding,

$$\mathfrak{m} \sum_{\kappa} G_{\kappa} \leq \sum_{\kappa} \left\{ g(\xi_{\kappa}) - g(\xi_{\kappa-1}) \right\} \int_{\kappa-1} \leq \mathfrak{M} \sum_{\kappa} G_{\kappa}. \tag{7}$$

But

$$\Sigma G_{\kappa} = g(\xi_n) - g(\xi_1).$$

Thus 7) gives

$$\sum \left\{ g(\xi_{\kappa}) - g(\xi_{\kappa-1}) \right\} \int_{\kappa-1} f dx = \Theta \left\{ g(\xi_{n}) - g(\xi_{1}) \right\}, \tag{8}$$

where

$$\mathfrak{m} \leq \Theta \leq \mathfrak{M}$$
. (9

Thus 5), 6), 8) give

$$\sum_{\alpha} f(\xi_{\kappa}) g(\xi_{\kappa}) \delta_{\kappa} = g(\xi_{1}) \int_{\alpha}^{b} f dx + \Theta \left\{ g(\xi_{n}) - g(\xi_{1}) \right\} + \sum_{\alpha} \sigma_{\kappa} g(\xi_{\kappa}). \tag{10}$$

In this equation let $\delta \doteq 0$. The limit of the left side is

$$\int_a^b fg dx$$
.

Also

$$\lim g(\xi_1) = g(a+0); \lim g(\xi_n) = g(b-0).$$

Let

$$|g(x)| < \Gamma;$$

then

$$|\Sigma \sigma_{\epsilon} g(\xi_{\epsilon})| < \Gamma \Sigma \sigma_{\epsilon}.$$

But

$$\Sigma \sigma_s \gtrsim \Omega f$$
, by 494.

As f is integrable,

$$\lim \Omega f = 0;$$

hence the last term of 10) has the limit 0.

Thus all the terms of 10), besides that in Θ , have finite limits. Hence the limit of Θ exists. Call it θ .

Hence

$$\mathfrak{m} \leq \theta \leq \mathfrak{M}$$
.

But F being a continuous function of x, it takes on the value θ for some point ξ in $\mathfrak A$ by 357

Hence

$$\theta = \int_{t}^{b} f dx$$

Passing now to the limit in 10), we have

$$\int_{a}^{b} f g dx = g(a+0) \int_{a}^{b} f dx + \left\{ g(b-0) - g(a+0) \right\} \int_{b}^{b} f dx \quad (11)$$

But since

$$\int_a^a = \int_a^t + \int_t^a,$$

we get 1) at once from 11)

548 If g(x) is not monotone the formula 1) of 545 may not be true as the following example shows

Let

$$f(x) = x^1 \qquad g(x) = \cos x$$

 $\int_{-\pi}^{\pi/2} x^2 \cos x \, dx > 0 \quad \text{by 627 1,}$

s not the integrand is never negative and is in general positive. On the other hand,

$$g(a+0) = cos - \pi/2 = 0$$
 $g(b-0) = cos \pi/2 = 0$

Hence the right side of 1) 645 is zero. The formula 1) is thus untrue in this case.

Primitive Functions

547 1 The theorem of 538 is of great importance in evaluating integrals For, to find the value of

$$J = \int_{a}^{x} f dz$$
, (1)

f(x) being limited and integrable in $\mathbb{X} = (x, x)$, we have only to seek a function F(x) which is one valued in \mathbb{X} and has f(x) as derivative. Then, as we saw,

$$J = F(x) - F(a) \tag{2}$$

Let G(x) be any other function which is one-valued in $\mathfrak A$ and has f(x) as derivative. Then

$$J = G(x) - G(\alpha). \tag{3}$$

Comparing 2), 3), we have

$$G(x) = F(x) + C$$

where C is a constant.

The functions F(x), G(x) are called *primitive functions of* f(x).

They are denoted by

 $\int f(x)dx,$

no limits of integration appearing in the symbol. Primitive functions are also called *indefinite integrals*. In contradistinction, integrals of the type 1) are called *definite integrals*.

2. Every formula of differentiation, as,

$$D_x F(x) = f(x),$$

f(x) being limited and integrable in an interval $\mathfrak A$, gives rise to a formula of integration, $\int f(x)dx = F(x).$

 J^{\bullet}

For reference, we add a short table of indefinite integrals.*

We observe, once for all, that in all formulæ involving indefinite integrals, we shall suppose that the integrands are one-valued, limited, and integrable in a certain interval \mathfrak{A} , while the functions outside the integral sign are one-valued in \mathfrak{A} .

548.
$$\int a dx = ax.$$

$$\int x^{\mu} dx = \frac{x^{\mu+1}}{\mu+1}, \qquad \mu \neq -1.$$

$$\int \frac{dx}{x} = \log |x|.$$

$$\int e^{x} dx = e^{x}.$$

^{*}An excellent table of integrals is "A Short Table of Integrals" by B. O. Peirce. Ginn & Co. Boston.

$$\int a^{x}dx = \frac{a^{x}}{\log a}, \quad a > 0.$$

$$\int \frac{dx}{a^{2} + x^{2}} = \frac{1}{a} \operatorname{arc} \operatorname{tg} \frac{x}{a}, \quad a \neq 0.$$

$$\int \frac{dx}{\sqrt{a^{2} - x^{2}}} = \operatorname{arc} \operatorname{sun} \frac{x}{a}, \quad a \neq 0.$$

$$\int \operatorname{sun} x \, dx = -\cos x$$

$$\int \cos x \, dx = \operatorname{sun} x$$

$$\int \operatorname{tan} x \, dx = -\log|\cos x|.$$

$$\int \cot x \, dx = \log|\sin x|$$

$$\int \operatorname{tan} x \operatorname{sec} x \, dx = \operatorname{sec} x.$$

$$\int \operatorname{ecc}^{2} x \, dx = \tan x$$

549 Not every limited integrable function in $\mathfrak{A}=(a,\,b)$ has a primitive, as we now show

Let f(x) be continuous in M. let

$$F(x) = \int_{-x}^{x} f dx, \quad a \le x \le b.$$

Then, by 537,

$$\frac{dF}{dx} = f(x), \qquad \text{in } \mathfrak{A}$$

Let us define a hanted function g(x) in $\mathfrak A$ as follows: it shall =f(x) except at points of a discrete aggregate in Δ , at which points $f(x)\neq g(x)$ Then, by 530,

$$\int_{a}^{x} g dx = F(x) \tag{1}$$

Suppose now g(x) had a primitive G(x) in \mathbb{N} Then, by 538,

$$\int_{a}^{x} g dx = G(x) - G(a). \qquad (2)$$

Comparing 1), 2), we get

Hence
$$G(x) = F(x) + C, \qquad C \text{ a constant.}$$

$$\frac{dG}{dx} = \frac{dF}{dx}, \qquad \text{in } \mathfrak{A};$$

$$f(x) = g(x), \qquad \text{in } \mathfrak{A},$$

which is a contradiction.

or

Methods of Integration

550. In order to find the primitive of a function f(x) we may proceed as follows: We first consult a table of indefinite integrals. If the integral we are seeking is not there, we try to transform it into one or more integrals which are in the table.

The principal transformations employed are:

- 1°. Decomposition of the integrand into a sum.
- 2°. Integration by parts.
- 3°. Change of variable.

We treat these now separately.

551. Decomposition of the integrand into a sum. This method, as its name implies, consists in breaking f(x) up into a sum of simpler functions. Thus, if

then
$$f(x) = f_1(x) + \dots + f_s(x),$$

$$\int f dx = \int f_1 dx + \dots + \int f_s dx.$$

$$Ex. 1.$$

$$J = \int \cos^2 x \, dx.$$

$$\cos^2 x = \frac{1 + \cos 2x}{2},$$

$$J = \frac{1}{2} \int dx + \frac{1}{2} \int \cos 2x \, dx$$

$$= \frac{1}{2} x + \frac{1}{2} \sin 2x.$$

$$J = \int \frac{a + bx}{a + \beta x} dx$$

$$\frac{\alpha + bz}{\alpha + \beta z} - \frac{b}{\beta} + \frac{\alpha\beta - \alphab}{\beta(\alpha + \beta z)}$$
 by 91, 2),

Now

$$J = \int_{\beta}^{b} \int_{\alpha}^{dx} dx + \frac{a\beta}{\beta} \int_{\alpha}^{\alpha} \frac{dx}{\alpha + \beta x}$$

Hence

$$\frac{dz}{\alpha + \beta z} = \frac{1}{\beta} \frac{d}{\alpha + \beta z} \left(\frac{\alpha + \beta z}{\beta} - \frac{1}{\beta} d \log (\alpha + \beta z) \right)$$

$$\int \frac{dz}{\alpha + \beta z} = \frac{1}{\beta} \log (\alpha + \beta z)$$

Thus

$$J = \frac{b}{a}z + \frac{a\beta - ab}{a^2}\log(\alpha + \beta z).$$

Integration by Parts

552 In the interval M let u(x) v(x) be one valued functions having limited integrable derivatives. Then

 $D \cdot uv = uv^t + vu^t$

Hence

$$\int uv'dx = uv - \int vu'dx.$$

The application of 1) to evalue

$$J = \int f dz$$
,

13 as follows We wrate

$$f = uv'$$

$$J = uv - \int vu' dx$$

Then 1) shows that

The determination of J is thus made to depend upon

553, EL 1.

(2

Then
$$u' = \frac{1}{x}, \quad v = \frac{1}{2}x^{2}.$$
Hence
$$J = \frac{1}{2}x^{2}\log x - \frac{1}{2}\int x \, dx$$

$$= \frac{x^{2}}{2}(\log x - \frac{1}{2}).$$
554. Ex. 2.
$$J = \int e^{ax}\sin bx \, dx, \quad a, b \neq 0.$$
Set
$$u = \sin bx. \quad v' = e^{ax}.$$
Then
$$u' = b\cos bx, \quad v = \frac{1}{a}e^{ax}.$$
Hence
$$J = \frac{1}{a}e^{ax}\sin bx - \frac{b}{a}\int e^{ax}\cos bx \, dx.$$
To find
$$K = \int e^{ax}\cos bx \, dx,$$
set
$$u = \cos bx, \quad v' = e^{ax}.$$
Then
$$u' = -b\sin bx, \quad v = \frac{1}{a}e^{ax}.$$
Hence
$$K = \frac{1}{a}e^{ax}\cos bx + \frac{b}{a}\int e^{ax}\sin bx \, dx$$

$$= \frac{1}{a}e^{ax}\cos bx + \frac{b}{a}\int e^{ax}\sin bx \, dx$$
This placed in 1) gives
$$e^{ax}(a\sin bx - b\cos bx)$$

The same method gives

$$\int e^{ax} \cos bx \, dx = \frac{e^{ax} \{a \cos bx + b \sin bx\}}{a^2 + b^2}.$$
 (3)

 $J = \frac{e^{ax} \{a \sin bx - b \cos bx\}}{a^3 + b^3}.$

Change of Variable

555. Let f(x) be continuous in the interval \mathfrak{A} . Let $u = \phi(x)$ have a continuous derivative $\phi'(x) \neq 0$ in \mathfrak{A} . Let \mathfrak{B} be the image of \mathfrak{A} , and $x = \psi(u)$ be the inverse function of ϕ . Then if

$$\int f[\psi(u)]\psi'(u)du = G(u), \quad valid \ in \ \mathfrak{B};$$
we have
$$\int f(x)dx = G[\phi(x)], \quad valid \ in \ \mathfrak{A}.$$
For,
$$\frac{dG[\phi(x)]}{dx} = \frac{dG(u)}{du} \cdot \frac{du}{dx}$$
(1)

386

As

$$\frac{dG}{du} = f[\psi(u)]\psi'(u) = f[\psi(u)]\frac{dx}{du}.$$

$$\frac{du}{dx} \quad \frac{dx}{du} = 1,$$

$$\frac{du}{dx} \frac{dz}{du} = 1,$$
Tes

1) gives
$$\frac{dG[\phi(x)]}{dx} = f[\psi(x)] = f(x).$$

556 Ex. 1
$$J = \int \frac{dx}{x \log x}$$

Set
$$u = \log x$$

Then
$$J = \int \frac{du}{u} = \log u = \log \log z.$$

557 Ex. 2.
$$J = \int \frac{dx}{x\sqrt{2}\,ax - a^3}$$
 Set
$$u = \sqrt{2}\,ax - a^3$$

Set
$$u = \sqrt{2} \cdot \alpha x - \alpha^{2}$$
Then
$$J = 2 \int \frac{du}{a^{2} + u^{2}} = \frac{2}{a} \arctan \frac{u}{a}$$

$$= \frac{2}{a} \arctan \sqrt{2} \cdot \frac{\sqrt{2} \cdot \alpha x - u^{2}}{a^{2}}$$

$$J = \int \frac{dz}{\sqrt{z^2 \pm a^2}}.$$

558 Ex. 3.
$$J = \int_{\sqrt{2\pi}} \frac{ds}{1-c^2}$$
Set
$$u = s + \sqrt{s^2 + c^2}$$
Then
$$J = \int_{u}^{du} = \log u$$

$$= \log(s + \sqrt{s^2 + c^2})$$

559 Ex. 4.
$$J = \int \frac{dz}{\sqrt{(z-z)(z-\delta)}}$$
Set
$$w = \sqrt{z-a}$$

 $J = 2 \int \frac{du}{\sqrt{21 + 2 \cdot n^2}},$

558 Er. 3.

INTEGRALS DEPENDING ON A PARAMETER

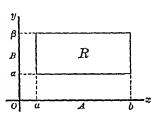

560. Let the rectangle bounded by the lines x = a, x = b, y = a, $y = \beta$ be denoted by

 $R = (\alpha, b, \alpha, \beta).$

Let $\mathfrak{A} = (a, b), \mathfrak{B} = (\alpha, \beta).$

Let f(x, y) be defined over R. If we give to y an arbitrary but fixed value in \mathfrak{B} , f(x, y) is a function

fixed value in \mathcal{B} , f(x, y) is a function of x defined over \mathfrak{A} . But since its value also depends on the particular value assigned to y, we say f is a function of x which depends upon the parameter y. If for each value of y in \mathfrak{B} , f(x, y) is a limited integrable function of x in \mathfrak{A} , we shall say it is regular in R. When f(x, y) is regular in R,

$$J(y) = \int_{a}^{b} f(xy) dx \tag{1}$$

defines a one-valued function of y, over the interval \mathfrak{B} .

In performing the integration indicated in 1), we consider y as constant and integrate with respect to x.

In the present section we propose to study the function J(y) with respect to continuity, differentiation, and integration.

Ex. 1.
$$J(y) = \int_0^{\pi} \frac{\sin xy}{e^x} dx.$$

 $\mathfrak{A} = (0, \pi)$, \mathfrak{B} any interval.

۲.

Ex. 2.
$$J(y) = \int_0^{\pi} \log(1 - 2y \cos x + y^2) dx.$$

 $\mathfrak{A} = (0, \pi)$, \mathfrak{B} any interval not including $y = \pm 1$. For, $\log u$ is continuous when u > 0. Here

$$u = 1 - 2y\cos x + y^2 = (y - \cos x)^2 + \sin^2 x \le 0$$

and hence u = 0 only for the points whose coördinates are

$$x = m\pi, y = (-1)^m.$$
 (3)

ÒΤ

Continuity

561. Let η be an arbitrary but fixed value of y in $\mathfrak{B} = (a, \beta)$.

Let us denote the line $y = \eta$ by H

Let $\phi(x)$ be defined over $\mathfrak{A}=(a,b)$

If for each $\epsilon > 0$, there exists a $\delta > 0$, such that

$$|f(x, \eta + h) - \phi(x)| < \epsilon$$
, (1
for each $0 < |h| < \delta$, and every x

for each $0 < |h| < \delta$, and every x in \mathfrak{A} , we say f(x, y) converges uniformly to $\phi(x)$ along the line H, or with respect to the line H

We denote this by

$$\lim_{x \to a} f(x, y) = \phi(x), \quad \text{uniformly},$$

$$f(x, y) = \phi(x), \quad \text{uniformly along } H$$

If in the relation 1), only positive values of h are considered, we

say f(x, y) converges on the right uniformly, etc.

If only negative values of h are considered, f(xy) converges on

the left uniformly, etc lif f(xy) converges uniformly to $f(x,\eta)$ with respect to the line H, we shall eay f(xy) is a uniformly continuous function of y with

respect to the line H, or along the line H If f(xy) is a uniformly continuous function of y with respect to each line $y = \eta$ in $\mathfrak{B} = (\alpha B)$, we shall say f(xy) is a uniformly continuous function of y in \mathfrak{B}

552 1 Let
$$f(x, y)$$
 be regular in any $R = (ab\gamma\beta)$, $a < \gamma < \beta$
Let $R \lim_{x \to 0} f(x, y) = \phi(x)$

uniformly along the line y = aLet $\phi(x)$ be limited and integrable in \mathfrak{A}

Then $R \lim_{x \to \infty} \int_{0}^{x} f(xy) dx = \int_{0}^{x} R \lim_{x \to \infty} f(xy) dx = \int_{0}^{x} \phi(x) dx \qquad (1)$

For. let

$$\Delta \approx \int_{a}^{b} f(x, a+h) dx - \int_{a}^{b} \phi(x) dx = \int_{a}^{b} |f(x, a+h) - \phi(x)| dx \qquad ($$

We have to show that

$$\epsilon > 0, \ \delta > 0, \ |\Delta| \le \epsilon, \ 0 < h < \delta.$$
 (3)

But by hypothesis, for each $\epsilon > 0$, there exists a $\delta > 0$, such that

$$|f(x, \alpha + h) - \phi(x)| < \frac{\epsilon}{b - a}$$
 (4)

for each $0 < h < \delta$, and any x in \mathfrak{A} .

Hence 3) follows from 2), 4), and 524, 2).

2. That the relation 1) may not hold when f(x, y) does not converge uniformly to $\phi(x)$, is shown by the following example:

Let

$$f(x, y) = \frac{y}{x^2 + y^2}, \quad \text{for } x \neq 0;$$

 $=0, \qquad \text{for } x=0.$

Here

$$R\lim_{y\to 0}f(x,\,y)=\phi(x)=0.$$

Hence

$$\int_0^1 \phi(x) dx = 0. \tag{5}$$

On the other hand,

$$J = \int_0^1 f dx = \int_0^1 \frac{y}{x^2 + y^2} dx = \text{arc tg } \frac{1}{y}, \quad y > 0.$$

Hence

$$R\lim_{y=0}J=\frac{\pi}{2}.$$

As 5), 6) have different values, the relation 1) does not hold here. Obviously f(x, y) does not converge uniformly to 0 in any interval containing the origin.

563. 1. As corollaries of 562 we have:

Let f(x, y) be regular in $R = (ab\alpha\beta)$. Let it be uniformly continuous in y, along the line $y = \eta$. Then

$$J(y) = \int_a^b f(x, y) dx$$

is a continuous function of y at η . $\alpha \leq \eta \leq \beta$.

2. Let f(x, y) be regular in $R = (ab\alpha\beta)$. Let it be a uniformly continuous function of y in \mathfrak{B} . Then J(y) is continuous in \mathfrak{B} .

3 If f(x, y) be continuous in $R(aba\beta)$, J(y) is continuous in B = (a, B)

This follows at once from 352

Example In 538 we proved the relation

$$\phi(\lambda) - \int_{0}^{\pi/2} \frac{dx}{1 + \lambda^{2} \ln^{2} x} = \frac{\pi}{2} \frac{1}{1 + |\lambda|}$$
(1)

564 The results of 562 563 may be generalized as follows

Let Δ be a discrete point aggregate in $\mathfrak A$. We can divide $\mathfrak A$ into two systems of intervals, $\mathbb C$ and $\mathfrak D$ such that $\mathbb C$ contains no point of Δ and the total length d of the intervals $\mathfrak D$ is as small as we please

We shall say f(x,y) converges uniformly to $\phi(x)$ along the line $y=\eta$ except at the points Δ when, for each $\epsilon>0$ and any C there exists a $\delta>0$, such that

$$|f(x, \eta + h) - \phi(x)| < \epsilon$$

for each 0 < |h| < 8 and every x in C

The terms f(x, y) converges on the right or on the left uniformly, except for the points Δ need no special explanation

Also the meaning of the term f(x, y) is uniformly continuous along the line y = n except for the points Δ is obvious

585 Let f(x, y) be regular in the rectangle $R(a, b, a, \beta)$ Let f converge uniformly to $\phi(x)$ along the line $y = \eta$ except for the points of a discrete aggregate Δ Let $\phi(x)$ be limited and integrable in $\mathfrak{A} = (a, b)$. Then

$$\lim_{x\to 0}\int_a^b f(x,y)dx = \int_a^b \lim_{x\to 0} f(x,y)dx = \int_a^b \phi(x)dx, \qquad \alpha \le \eta \le \beta$$

$$D = \int_{a}^{b} f(x, \eta + h) dx - \int_{a}^{b} \phi(x) dx$$

We must show that

$$\epsilon > 0, \quad \delta > 0, \quad |D| < \epsilon, \quad 0 < |h| < \delta.$$
 (1)

Since f is limited in R, and ϕ in \mathfrak{A} ,

$$|\phi(x)|$$
, $|f(x,y)| < M$, in R .

Choosing $\epsilon > 0$ small at pleasure, and then fixing it, we choose the system $\mathfrak D$ such that its length

$$d < \frac{\epsilon}{4 M}$$

Then

$$D = \int_{\mathbb{C}} \{f(x, \eta + h) - \phi(x)\} dx + \int_{\mathfrak{D}} \{f(x, \eta + h) - \phi(x)\} dx.$$

Hence

$$|D| \le \left| \int_{\mathfrak{C}} \right| + \left| \int_{\mathfrak{D}} \right|. \tag{2}$$

But

$$\left|\int_{\mathfrak{D}}\right| < \frac{\epsilon}{2}$$

On the other hand, by hypothesis,

$$|f(x, \eta + h) - \phi(x)| < \frac{\epsilon}{2(b-a)}$$

for each $0 < |h| < \delta$, and every x in \mathfrak{C} . Hence

$$\left|\int_{\mathfrak{C}}\right| \leq \frac{\epsilon}{2}$$

Hence 2) gives

$$|D| < \frac{\epsilon}{2} + \frac{\epsilon}{2}$$

which proves 1).

566. As corollary we have:

Let f(x, y) be regular in the rectangle $R = (a, b, \alpha, \beta)$. Let it be uniformly continuous in y along the line $y = \eta$, except for the points of a discrete aggregate Δ . Then

$$J(y) = \int_a^b f(x, y) dx$$

is continuous at n,

$$\alpha < \eta < \beta$$
.

Differentiation

567 1 1º Let f(x, y), $f'_y(x, y)$ le regular en R = (abaS)

2º Let f' be uniformly continuous in y along the line $y = \eta$, ex cept for the points of a discrete aggregate

Let

$$J(y) = \int_{0}^{x} f(x, y) dx$$

Then

$$J'(\eta) = \int_{-1}^{1} f'_{\alpha}(x, \eta) dx \qquad \alpha \leq \eta \leq \beta$$

a

For,
$$\frac{\Delta J}{\Delta \eta} = \frac{J(\eta + h) - J(\eta)}{h} = \int_{a}^{b} \frac{f(x, \eta + h) - f(x, \eta)}{h} dx \qquad (2)$$

But by the Law of the Mean.

$$\frac{f(z,\eta+h)-f(z,\eta)}{f(z,\eta)}=f_{x}^{\eta}(z,\zeta),$$

where & hes between n and n+ h and depends on z and h But by 2°. $f'_n(x, \zeta) = f'_n(x, \eta) + \sigma$

where

$$\lim \sigma = 0, \quad uniformly \ except \ for \ \Delta.$$

Thus

$$\frac{\Delta J}{\Delta \eta} = \int_{a}^{b} f_{s}'(z, \eta) dz + \int_{a}^{b} \sigma dz,$$
(3)

which gives 1), on passing to the limit, h = 0

2 As corollary we have

Let $f(x, y), f_*(x, y)$ be continuous in the rectangle (aba\beta) Then

$$\frac{d}{dy}\int_{a}^{b}f(x,y)dx = \int_{a}^{b}f_{y}(x,y)dx \qquad \alpha \leq y \leq \beta \quad (3)$$

3 Criticism Many text books give the following incorrect demonstration of 1 From 2) we have, changing slightly the notation, (4

 $\frac{dJ}{dv} = \lim \frac{\Delta J}{\Delta v} = \lim \int_{0}^{\infty} \frac{\Delta f}{\Delta v}$

It is now assumed, without further restriction, that

$$\lim_{a} \int_{a}^{b} \frac{\Delta f}{\Delta y} = \int_{a}^{b} \lim_{a} \frac{\Delta f}{\Delta y}.$$

$$\lim_{a} \frac{\Delta f}{\Delta y} = \frac{\partial f}{\partial y},$$

$$\frac{dJ}{dy} = \int_{a}^{b} \frac{\partial f}{\partial y} dx.$$
(5)

As

4) and 5) give

But we have already seen in 562, 2, that an interchange of the symbols

lim, ∫

is not always permissible.

4. Example. $J = \int_0^{\pi} \log(1 - 2y \cos x + y^2) dx. \tag{6}$ Here, f(x, y) and

 $f_y'(xy) = \frac{2(y - \cos x)}{1 + 2x \cos x + x^2}$

Here, f(x, y) and

are continuous in the rectangle $(0, \pi, \alpha, \beta)$ if (α, β) does not contain the points $y = \pm 1$. Cf. 560, Ex. 2. Hence

$$\frac{dJ}{dy} = 2 \int_0^{\pi} \frac{(y - \cos x)dx}{1 - 2y\cos x + y^2}, \quad |y| \neq 1.$$
 (7)

5. The following is an example where the conditions of theorem 1 are not satisfied, and where differentiation under the integral sign leads to a wrong result.

Let

$$F(x, y) = \frac{xy}{\sqrt{x^2 + y^2}}, \qquad \text{except at origin;}$$

$$= 0, \qquad \text{at origin.}$$

$$D_z F(x, y) = \frac{y^3}{(x^2 + y^2)^{\frac{5}{2}}}, \qquad \text{except at origin;}$$

$$= 0, \qquad \text{at origin.}$$
Hence
$$\int_0^1 D_z F(xy) dx = \frac{y}{\sqrt{1 + v^2}}, \qquad y \text{ arbitrary.}$$

Let

$$f(z, y) = \frac{y^{\delta}}{(z^{2} + y^{2})^{\frac{1}{2}}}, \quad \text{except at origin },$$

$$= 1, \quad \text{at origin.}$$

Then

Hence

$$J(y) = \int_0^1 f dx = \int_0^1 D_x F dx = \frac{y}{\sqrt{1+y^2}}$$

$$J'(0) = 1$$
 (8
On the other band, $f_b(x, 0) = 0$, x arbitrary

Hence

The equations 8) 9) show that in this case differentiation under the integral sign is not permissible. In fact, we observe here that

$$f_3(z, y) \approx \frac{3 x^4 y^2}{(z^2 + y^2)^{\frac{3}{2}}},$$
 except at origin,
= 0 at origin

and is therefore not immed about the origin. Thus, condition 1° of theorem 1 is not fulfilled.

Integration

1 Let f(xy) be continuous in the rectangle $R = (a, b, \alpha, \beta)$ Since

$$\int_{a}^{x} f dx \qquad a \leq x \leq b \tag{1}$$

is a continuous function of y by 563, 2, it is integrable in (a, B) Therefore

$$\int_{-\infty}^{\infty} dy \int_{-\infty}^{\infty} f dx \qquad (2)$$

(8

is convergent for each a < v < 8

The integral 2) is obtained from 1) by integrating with respect to the parameter v It is called a double iterated integral, or more shortly, when no ambiguity can arise, a double integral

2 Let f(x, y) be continuous in R = (abaβ) Let

$$F(x, y) = \int_{0}^{x} dy \int_{0}^{x} f dx$$
, $x, y \in \mathbb{R}$

Then

$$F_{xx}^{\prime\prime} = F_{xx}^{\prime\prime} = f(xy), \quad \text{in } R$$

$$F'_{y} = \int_{a}^{x} f dx,$$

$$F'_{yx} = f(xy).$$
(4)

On the other hand, by 567, 2,

$$F'_{x} = \int_{\alpha}^{y} dy \frac{\partial}{\partial x} \int_{a}^{x} f dx$$

$$= \int_{a}^{y} f dy, \text{ by 537.}$$

$$F''_{xy} = f(xy). \tag{5}$$

Hence, by 537,

The relation 3) follows now from 4), 5).

Inversion of the Order of Integration

569. The integral of 568, viz.

$$\int_{a}^{y} dy \int_{a}^{x} f dx, \tag{1}$$

is obtained by integrating first with respect to x, and then with respect to y.

But we might have integrated in the inverse order, getting

$$\int_{a}^{x} dx \int_{a}^{y} f dy.$$
 (2)

It frequently happens that the integrals 1), 2) are equal, and this fact is of greatest importance in transforming such integrals. When these two integrals are the same, we say that we can invert the order of integration, or the integral 2) admits inversion. We give now a simple case when this inversion is possible. Later we shall give a broader criterion.

570. 1. Let f(xy) be limited in the rectangle $R = (ab\alpha\beta)$. Let it be continuous in R, except possibly along a finite number of lines parallel to the x or y axes, along which, however, f is integrable. Then

$$\int_{a}^{\beta} dy \int_{a}^{b} f(xy) dx = \int_{a}^{b} dx \int_{a}^{\beta} f(xy) dy.$$
 (1)

Case 1 Let f be continuous in R without exception

We saw in 568 that

$$\frac{\partial}{\partial x} \quad \frac{\partial F}{\partial y} = f(xy)$$

Hence, by 538,

$$\int_{a}^{b} f dx = \frac{\partial F(b \ y)}{\partial y} - \frac{\partial F(\alpha \ y)}{\partial y}$$

For the same reason,

$$\int_{a}^{b} dy \int_{a}^{b} f dx = \int_{a}^{b} \frac{\partial F(b, y)}{\partial y} dy - \int_{a}^{b} \frac{\partial F(a, y)}{\partial y} dy$$

$$= F(b, B) - F(b, a) - F(a, B) + F(a, a) \qquad (2)$$

Similarly,

$$\int_{a}^{b} f dy = \frac{\partial F(x\beta)}{\partial x} - \frac{\partial F(x\alpha)}{\partial x}$$

(3

and $\int_a^b dx \int_a^b f dy = F(b\beta) - F(a\beta) - F(b\alpha) + F(a\alpha)$

Case 2 I et f be continuous in R, except for points on the line x=b

By I we have a < b < b, $\int_{a}^{a} dx \int_{a}^{b} f dy = \int_{a}^{b} dy \int_{a}^{b} f dx \qquad (4$

Moreover by 563, 3,

 $\int_{a}^{a} f(x \ y) dy$

being a continuous function of x in (a, b) except possibly at b, and limited in (a, b),

 $\int_a^b dx \int_a^b f dy$

exists Now, by 536.

$$\lim_{\delta \to 0} \int_a^b dx \int_a^b f dy = \int_a^b dx \int_a^b f dy \tag{}$$

On the other hand,

$$\int_a^b f dx = \int_a^b f dx - \int_b^b f dx.$$

But since f is limited, let

$$|f| \leq M$$
, in R .

Then

$$\left|\int_{b}^{b} f dx\right| \leq M(b-b').$$

Hence the right side of 4) gives

$$\int_{a}^{\beta} dy \int_{a}^{b} f dx = \int_{a}^{\beta} dy \int_{a}^{b} f dx - \int_{a}^{\beta} dy \int_{b'}^{b} f dx.$$

Thus

$$\left| \int_a^{b'} dx \int_a^{\beta} f dy - \int_a^{\beta} dy \int_a^b f dx \right| \leq M(\beta - \alpha)(b - b').$$

Letting $b' \doteq b$ and using 5), we get 1).

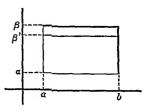

Evidently the same reasoning applies when f is continuous in R, except on one of the sides of R parallel to x-axis.

Case 3. Let f be continuous in R except on the two lines, x = b, $y = \beta$.

Let $\alpha < \beta' < \beta$. Then, by Case 2,

$$\int_{a}^{\beta} dy \int_{a}^{b} f dx = \int_{a}^{b} dx \int_{a}^{\beta} f dy.$$

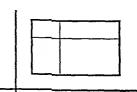

We can reason with this equation in the same manner as we did with 4). This proves the theorem also for this case.

Case 4. If f(xy) is discontinuous within R, we have only to divide R into four rectangles \Re , as in the figure.

Then each of the rectangles R falls under Case 3. By breaking up the given

integrals into these rectangles \Re , we prove 1) readily.

- Case 5 General Case By breaking R into smaller rectangles R, bounded by the lines on which the points of discontinuity lie, we reduce this case to Case 4
- 2 We have shown in 1 that inversion is permissible when f(zy) is continuous, except at points lying on a finite number of lines parallel to the x and y sxes. It will be shown in Chapter XVI that inversion is permissible under much wider circumstances.

The points of discontinuity may be on an infinite number of sines, moreover these lines do not need to be parallel to the axes they do not even need to be right lines

Example We saw by 538 2, that

$$\int_{1}^{\pi/2} \frac{dz}{1+y^{2} \tan^{2} z} = \frac{\pi}{2} \frac{1}{1+|y|}$$

Hence

$$J = \int_0^1 dy \int_0^{\pi/2} \frac{dz}{1 + y^2 \tan^2 z} - \frac{\pi}{2} \int_0^1 \frac{dy}{1 + y} = \frac{\pi}{2} \log 2$$
 (1)

As the integrand is limited in the rectangle $\begin{pmatrix} 0 & 0 & 1 \\ 2 & 0 & 1 \end{pmatrix}$ and is discontinuous only when $z = \pi/2$ we can invert the order of integration. Hence

$$J = \int_0^{\pi/2} dx \int_0^1 \frac{dy}{1 + y^2 \tan^2 x} = \int_0^{\pi/2} dx \left[\frac{\arctan (y \tan x)}{\tan x} \right]_0^1$$

$$= \int_0^{\pi/2} \frac{dx}{\tan x}$$
(2)

Thus 1), 2) give

$$\int_{4}^{x/2} \frac{x \, dx}{\tan x} = \frac{\pi}{2} \log 2.$$

CHAPTER XIV

IMPROPER INTEGRALS. INTEGRAND INFINITE

Preliminary Definitions

571. 1. Up to the present, we have considered only integrals

$$\int_a^b f(x)dx,$$

in which the integrand is limited, as well as the interval of integration $\mathfrak{A} = (a, b)$.

It is desirable to extend the definition of an integral to embrace integrands and intervals of integration which are not limited. Such integrals, we said, are called improper integrals.

In this chapter we consider improper integrals for which $\mathfrak A$ is limited, and f(x) is unlimited in $\mathfrak A$.

$$J = \int_0^x \frac{dx}{x}, \quad K = \int_0^1 \frac{dx}{\sqrt{1 - x^2}},$$

are examples of such integrals.

- 2. The reader will observe that the integrand of J is not defined at x = 0, and the integrand of K at x = 1. When convenient, we may assign to the integrand at such points any value at pleasure. Cf. 598.
- 572. Let f(x) have a finite number of points of infinite discontinuity in \mathfrak{A} , 347, $c_1, c_2, \cdots c_m$.

We shall call these singular points, and say f(x) is in general limited in \mathfrak{A} ; or that it is limited except at these points. Let us inclose each point c_x within a little interval \mathfrak{S}_x containing no other

singular points Let $\mathfrak B$ be what is left after removing the intervals G_n from $\mathfrak N$ On varying the intervals G_n $\mathfrak B$ will vary $\mathbb N$ if no each choice of $\mathfrak B$, f(x) is integrable in $\mathfrak B$, we say f(x) is regular in $\mathfrak A$ except at the points e_1 e_n , or we say f(x) is in general resular in $\mathfrak A$.

573 1. Let f(x) be regular in $\mathfrak{A} = (a \ b)$ except at b If

$$\lim_{\beta \to 0} \int_a^\beta f(x) dx, \quad a < \beta < b, \quad (1)$$

is finite, we say f(x) is integrable in X and define the symbol

$$J = \int_a^b f(x) dx$$

to be this limit

400

Similarly, if f(x) is regular in A except at a and

$$\lim_{x \to \infty} \int_{-x}^{x} f(x) dx, \quad a < a < b, \tag{2}$$

is finite, we say f(x) is integrable in A and define J to be this limit

Finally, if f(x) is regular in X except at a, b, and

$$\lim_{z \to 1} \int_{z}^{\beta} f(z) dz \qquad a < \alpha < \beta < \delta, \qquad (8)$$

is finite, we say f(x) is integrable in X and define J to be this limit

When these limits 1), 2), 3) are fin to we say J is finite or con vergent. When these limits are infinite, we say J is infinite. If these limits do not exist, finite or infinite, we say J does not exist.

2 In

$$J = \int_{-1}^{1} f dx$$

we have taken a < b Precisely similar definitions would apply if a > b

Obviously,

$$\int_{0}^{x} f dx = -\int_{0}^{x} f dx \qquad (4)$$

For, to fix the ideas, suppose f(x) regular except at a, and let the integral on the right be convergent. Then, if $a < \alpha < b$,

$$\int_a^b f dx = -\int_b^a f dx, \qquad \text{by 524, 1)}.$$

Passing to the limit, we get 4).

574. 1. Let f(x) be regular in $\mathfrak{A} = (a, b)$, except at b. For f(x) to be integrable in \mathfrak{A} , according to the definition just given, it is necessary and sufficient that

$$\epsilon > 0, \qquad \delta > 0, \qquad \left| \int_a^{\beta} f dx - \int_a^{\beta} f dx \right| < \epsilon$$

for any pair of numbers β , β' within $(b-\delta, b)$, by 284.

Since

$$\int_{a}^{\beta'} - \int_{a}^{\beta} = \int_{b}^{\beta'},$$

it is necessary and sufficient that

$$\left| \int_{\beta}^{\beta'} f(x) dx \right| < \epsilon. \tag{1}$$

The integral

$$\int_{\beta}^{\beta} f(x) dx, \qquad b - \delta < \beta, \, \beta' < b, \qquad (2)$$

is called the left-hand singular integral of norm δ for the point b. Similarly,

 $\int_a^{a'} f dx, \qquad a < \alpha, \ \alpha' < a + \delta,$

is called the right-hand singular integral of norm δ for the point a. We have thus this result:

Let f(x) be regular in $\mathfrak{A} = (a, b)$ except at an end point, say b. For f(x) to be integrable in \mathfrak{A} , it is necessary and sufficient that the singular integral at b have the limit 0; i.e.

$$\lim_{\delta \to 0} \int_{\beta}^{\beta'} f(x) dx = 0, \qquad a < b - \delta < \beta, \ \beta' < b.$$

2. When a singular integral such as 2) converges to zero as its norm $\delta \doteq 0$, we shall say the singular integral is evanescent.

3. Let f(x) be regular in $\mathfrak{A} = (a, b)$ except at the end points a, b For

$$J = \int_{-1}^{1} f(x) dx$$

to be convergent, at is necessary and sufficient that the singular integrals

$$\int_{a}^{a} f dz, \quad \int_{a}^{b} f dz, \quad a < a' < a'', \quad b' < b'' < b$$

he enanescent

It is necessary For, when J is convergent,

$$\epsilon > 0$$
, $\delta > 0$, $\left| J - \int_{-\delta}^{\delta} \right| < \frac{\epsilon}{\alpha}$, $\alpha < \alpha < \alpha + \delta$, $\delta - \delta < \beta < \delta$

Also $\left|J-\int_{a}^{b}\right|<\frac{\epsilon}{2}, \quad a<\alpha'<\alpha+\delta$ Adding, $\left|\int_{a}^{a}\right|<\epsilon, \quad a<\alpha,\alpha'<\alpha+\delta$

Thus the singular integral at σ is evanescent. The same is true for δ

It is sufficient. For the singular integrals being evanescent, we have

 $\epsilon > 0$, $\delta > 0$, $\left| \int_{\epsilon'}^{\epsilon'} \left| < \frac{\epsilon}{2} \right|$, $\left| \int_{\epsilon'}^{\epsilon'} \left| < \frac{\epsilon}{2} \right|$

Hence

$$\left|\int_{0}^{\infty}-\int_{0}^{\infty}\left|\leq\left|\int_{0}^{\infty}\right|+\left|\int_{0}^{\infty}\right|<\varepsilon$$

Hence

$$\lim_{x \to a} \int_a^b f dx, \quad a < a < \beta < b$$

is finite, and hence by definition J is convergent.

575 Ex. 1.

$$J = \int_0^1 \frac{dx}{\sqrt{1-x^2}}$$

Now, for $0 < \beta < 1$, $F(x) = \int_{0}^{\beta} \frac{dx}{\sqrt{1 - x^2}} = \arcsin \beta$ As

$$\lim_{\beta=1} \arcsin \beta = \pi/2,$$

 $J=\pi/2$.

The singular integral at 1 is

$$\int_{\beta}^{\beta} \frac{dx}{\sqrt{1-x^2}} = \arcsin \beta' - \arcsin \beta.$$

As

$$\lim_{x\to 1} \arcsin x = \pi/2,$$

the difference on the right of 1) is numerically $<\epsilon$ in $V_{\delta}(1)$, for a sufficiently small δ .

Ex. 2,

Here, for $0 < \alpha < 1$.

$$J = \int_0^1 \frac{dx}{x}.$$
$$\int_0^1 \frac{dx}{x} = -\log \alpha.$$

But

$$R\lim_{\alpha=0}\log\alpha=-\infty.$$

Hence J is infinite, viz. $J = + \infty$.

The singular integral at 0 is

$$\int_{\alpha'}^{\alpha''} \frac{dx}{x} = \log \frac{\alpha''}{\alpha'}, \quad 0 < \alpha' < \alpha'' < \delta.$$

But

$$\lim_{\delta=0}\log\frac{\alpha''}{\alpha'}$$

does not exist, by 321.

Ex. 3.

$$J = \int_0^1 x^{\lambda - 1} dx, \qquad \lambda > 0.$$

Now, if $0 < \alpha < 1$,

$$\int_{\alpha}^{1} x^{\lambda-1} dx = \frac{1-\alpha^{\lambda}}{\lambda}.$$

But

$$\lim_{\alpha=0}\frac{1-\alpha^{\lambda}}{\lambda}=\frac{1}{\lambda}, \quad \text{by 299, 2.}$$

Hence

$$J=\frac{1}{\lambda}$$

576. Let f(x) be integrable in $\mathfrak{A} = (a, b)$, and regular except at a, b. Let c be any point within \mathfrak{A} . Then

$$J = \int_a^b f dx = \int_a^c f dx + \int_c^b f dx. \tag{1}$$

For, since J is convergent,

$$\epsilon > 0$$
, $\delta > 0$, $\left| J - \int_{a}^{\beta} \left| < \frac{\epsilon}{2}, \ a < \alpha < \alpha + \delta; \ b - \delta < \beta < b.$ (2)

By 574, 3, the integrals

are convergent We can therefore take & such that also

$$\left|\int_{\epsilon}^{\epsilon} - \int_{\epsilon}^{\epsilon}\right| < \frac{\epsilon}{4}, \quad \left|\int_{\epsilon}^{\delta} - \int_{\epsilon}^{\epsilon}\right| < \frac{\epsilon}{4}$$

Adding these last inequalities gives

$$\left| \left(\int_{s}^{s} + \int_{s}^{s} \right) - \int_{s}^{s} \left| < \frac{s}{2} \right| \right|$$
 (3)

Adding 2), 3) gives

$$\left|J-\left(\int_{a}^{t}+\int_{t}^{t}\right)\right|<\epsilon.$$

From this follows 1)

577 1 Definition We can now generalize as follows. Let f(x) be regular in $\mathfrak A$ except at the singular points

If f(x) is integrable in

$$(a, c_1), (c_1 c_2), (c_m, b),$$

we say f(x) is integrable in A and set

$$\int_{a}^{b} f dx = \int_{a}^{b} f dx + \int_{a}^{b} f dx + \int_{a}^{b} f dx + \int_{a}^{b} f dx.$$

2 We can therefore say

Let f(x) be regular in $\mathbb{N} = (a, b)$, except at certain points $c_1 \ c_2 \ c_m$. For f(x) to be integrable in \mathbb{N} it is necessary and sufficient that the singular integrals at $c_m c_n$ be evanescent

3 From this follows at once

If f(x) is in general regular and is integrable in A, it is integrable in any partial interval of A

4. To avoid confusion and errors of reasoning, the reader should remember that, when f(x) is not limited in $\mathfrak A$ but yet integrable in $\mathfrak A$, there are only a finite number of singular points in $\mathfrak A$; and f is limited and integrable in any partial interval of $\mathfrak A$, not embracing one of the singular points.

Criteria for Convergence

578. 1. The integral

$$K = \int_a^b |f(x)| dx$$

is called the adjoint integral of

$$J = \int_a^b f(x) dx.$$

We write

$$K = AdjJ$$
.

Let f(x) be in general regular in \mathfrak{A} . If the adjoint of

$$J = \int_{\mathfrak{A}} f dx$$

is convergent, J is convergent.

Let c be a singular point of f(x). We wish to show that the singular integrals at this point are evanescent. To fix the ideas let us consider the left-hand singular integral. By 528,

$$\left| \int_{\gamma}^{\gamma} f dx \right| \le \int_{\gamma}^{\gamma} |f| dx, \quad c - \delta < \gamma < \gamma' < c.$$

By hypothesis, the integral on the right vanishes in the limit $\delta = 0$. Hence the integral on the left, which is the left-hand singular integral at c, is evanescent.

When AdjJ is convergent in \mathfrak{A} , J is said to be absolutely convergent in \mathfrak{A} and f(x) is absolutely integrable in \mathfrak{A} .

2. Let f(x) be absolutely integrable in \mathfrak{A} , and in general, limited. Then f is absolutely integrable in any partial interval of \mathfrak{A} .

The demonstration is obvious.

3. The reader should note that f(x) may be integrable in \mathfrak{A} and yet not absolutely integrable, as the following example shows.

Let us divide the interval # ... (0 1) into partial intervals by inserting the points, In the interval $g_n - \left(\frac{1}{n+1}, \frac{1}{n}\right)$ n=1, 2 Let us erect a rectangle P_n of area

Let these rectanates i e alternately above and below the x-axis. In the interval n. excluding the left-hand end point let f(z) - he ght of B, taken positively or negatively accordingly as R. is above or below the axis. Then f(x) has a singular po at at x=0

We have now

is convergent

$$\int_{0}^{1} f dx - \lim_{n \to \infty} \int_{1}^{1} f dx = \lim_{n \to \infty} \int_{1}^{1} f dx - \lim_{n \to \infty} \left(1 - \frac{1}{2} + \frac{1}{3} - \frac{+\frac{(-1)^{n}}{n-1}}{n-1}\right)$$

$$\int_{1}^{1} f dx - \lim_{n \to \infty} \left(1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{n-1}\right)$$

$$\int_{1}^{1} f \, dx = \lim_{n \to \infty} \left(1 + \frac{1}{2} + \frac{1}{3} + \dots + \frac{1}{m}\right)$$

As the reader probably knows or as will be shown later the first I mit is finite. the second infinite. Thus / is ntegrable but not absolutely integrable in al.

4 The reader should note this difference between proper and improper integrals, $J = \int_{0}^{x} f(x) dx$

If J is an improper integral we have just seen that J is conver gent if $K = \int_{0}^{x} |f(x)| dx$

But if J is a proper integral, we saw in 528 2, that we could not conclude the existence of J from that of K On the other hand if J is a proper integral, the existence of K

follows from that of J, by 507 while if J is an improper integral we cannot conclude the convergence of K from that of J by 3

579 1 The μ test Let f(x) be regular in A = (a b) except at a For some 0 < \u03b1<1 and W>0 let there exist a Vo(a) such that

$$(x-a)^a f(x) < \mathcal{V}$$
 in \mathcal{V}^a

Then f(x) is absolutely integrable in \mathfrak{A} Consider the singular integral at a We have

$$0 \le \int_a^a |f| dx \le \int \frac{Mdx}{(x-x)^n} = \prod_{i=1}^n \left\{ (\alpha'-a)^{1/n} - (\alpha'-a)^{1/n} \right\},$$

which vanishes in the limit by 299 2

2. As a corollary we have:

Let f(x) be regular in $\mathfrak{A} = (a, b)$ except at a.

For some $0 < \mu < 1$, let

$$R\lim_{x\to a}(x-a)^{\mu}|f(x)|$$

be finite. Then f(x) is absolutely integrable in \mathfrak{A} .

Ex. 1.

is convergent.

convergent.

For, by 454, Ex. 2,

 $\int_0^1 \log x \, dx$

 $R\lim_{x=0}x^{\mu}|\log x|=0, \qquad \mu>0.$

Ex. 2.

is convergent.

For,

 $\int_0^1 x^{-\frac{1}{2}} \sin \frac{1}{x} \, dx$

$$R \lim_{x=0} x^{\mu} \cdot \left| x^{-\frac{1}{3}} \sin \frac{1}{x} \right| = 0, \quad \mu > \frac{1}{3}.$$

580. Let f(x) be regular in $\mathfrak{A} = (a, b)$ except at a. In $V^*(a)$ let f(x) have one sign σ , while

 $(x-a)\sigma f(x) > M > 0.$

Then

$$J = \int_a^b f dx = \sigma \infty.$$

For, let

$$a < \alpha < c < \alpha + \delta$$
.

Then

$$\left| \int_{a}^{c} f dx \right| \ge \int_{a}^{c} \frac{M}{x - a} dx = M \log \frac{c - a}{a - a}$$

 $\doteq +\infty$, when $\alpha \doteq a$.

Hence

$$\int_a^c f dx = \sigma \cdot \infty.$$

Example.

$$J = \int_0^1 \frac{dx}{1 - \alpha^2} = +\infty.$$

For,

$$(1-x)f(x) = \frac{1}{1-x} > \frac{1}{2}$$

for x near 1.

Let
$$\lambda = \lim_{x \to a} (x - a) f(x)$$

exist If f(x) is integrable, λ must be 0

Let us prove the theorem by showing that the contrary leads to a contradiction

To fix the ideas suppose $\lambda > 0$ Then, for each μ such that

$$0 < \mu < \lambda$$

there exists a V. (a) such that

$$(x-a)f(x)>\mu$$
, in V_i^* .

Then the singular integral,

$$\int_{-\infty}^{\infty} f dx = +\infty$$
, by 580

Hence f is not integrable in A

582 The orders of 579, 589 admit a simple geometric inter pietation

Consider the family of curves

$$H_{\mu} \qquad (x-a)^{\mu}y = M \qquad M>0, \quad \mu>0,$$

in the vicinity RVo(a)

of the figure

The curve H, is a hyperbola. If #<1, H hes below II, while if \$\mu > 1, H_ has above H_ Further more, if $1 > \mu > \mu'$ H, hes above H, The curves H all cut each other at the point x = a + 1 As we are only interested in these curves in the Immediate vicinity of the point x=athe point a+1 lies beyond the range

The u tests may now be stated as follows

If in some $V^{\bullet}(a)$ | f(x)| remains below some H, which has below H_i , f(x) is integrable If, on the other hand f(x) has one sign in $V^{\bullet}(a)$, and |f(x)| remains above H_1 , the corresponding integral is infinite

$$J = \int_0^1 \frac{dx}{\sqrt{1-x^2}}$$

The only singular point is x = 1. Let us apply the μ test at this point. Since

$$f(x) = \frac{1}{\sqrt{1-x^2}} = \frac{1}{\sqrt{1-x}} \cdot \frac{1}{\sqrt{1+x}},$$

we see that

$$L \lim_{x=1} (1-x)^{\frac{1}{2}} f(x) = \frac{1}{\sqrt{2}}$$

We may therefore take $\mu = \frac{1}{2}$, and J is convergent.

584. Ex. 2.

$$J = \int_{1}^{\frac{1}{\kappa}} \frac{dx}{\sqrt{x^{2} - 1 \cdot 1 - \kappa^{2}x^{2}}}, \quad 0 < \kappa < 1.$$

The singular points are 1, $\frac{1}{2}$.

Consider the point x = 1.

$$\sqrt{x^2 - 1 \cdot 1 - \kappa^2 x^2} = \sqrt{x - 1} \sqrt{x + 1 \cdot 1 - \kappa^2 x^2}.$$

Hence

$$R\lim_{x=1} (x-1)^{\frac{1}{2}} f(x) = \frac{1}{\sqrt{2(1-\kappa^2)}}$$

In the μ test we can therefore take $\mu = \frac{1}{2}$.

Consider the point $x = \frac{1}{x}$.

Λs

$$L \lim_{x=\frac{1}{2}} \left(\frac{1}{\kappa} - x \right)^{\frac{1}{2}} f(x) = \frac{\kappa^{\frac{1}{2}}}{\sqrt{2(1-\kappa^{2})}},$$

we can take $\mu = 1$ at this point.

Thus J is convergent.

585, Ex. 3.

$$J = \int_0^x \log \sin x \, dx, \qquad 0 < x < \pi.$$

The singular point is x = 0. We saw

$$\lim_{x \to 0} \frac{\sin x}{x} = 1.$$

Hence

$$\sin x = xq(x),$$

where

$$\lim_{x\to 0}g(x)=1.$$

Thus

$$\log \sin x = \log x + \log a(x).$$

and

$$x^{\mu} \log \sin x = x^{\mu} \log x + x^{\mu} \log g(x), \qquad \mu > 0.$$

But

$$\lim_{x\to 0} x^{\mu} \log x = 0, \qquad \lim_{x\to 0} x^{\mu} \log g(x) = 0.$$

Henee

$$\lim x^{\mu} \log \sin x = 0.$$

Thus in the μ test, we can take for μ any positive number < 1. Hence J is convergent.

110

The singular point of the integrand f(x) is x=0 In its vicinity $V^{\bullet}(0)$, f(x)

has one sign e = +1Then by 5"9, Ju convergent for $\mu < 1$ and, by 580, it is divergent for $\mu \le 1$.

587 Ex. 5
$$J = \int_{a}^{a_{\text{min}} x} dx, \quad a > 0$$

The only singular point is x = 0 In $V^*(0)$, the integrand has one sign $e \approx +1$. As

we see, by 579, that J is convergent if $\mu < 2$, and, by 580, that it is divergent, if $\mu \leq 2$

588 Logarithmic tests Let f(x) be regular in $\mathbb{X} = (a, b)$, except at a For some M > 0, $\lambda > 1$, s, let there exist a $V_{\bullet}^{\bullet}(a)$, such that in it

$$(x-a) l_1 \frac{1}{x-a} l_1 \frac{1}{x-a} l_1 \frac{1}{x-a} l_1 \frac{1}{x-a} l_1^{\lambda} \frac{1}{x-a} |f(x)| < M \quad (1)$$

Then f is absolutely integrable in A

By 389, 5), for x > a sufficiently near a, and s = 1, 2, ...

$$D_{s}l_{s}^{1-\lambda}\frac{1}{x-a} = \frac{\lambda - 1}{(x-a)l_{1}\frac{1}{x-a}l_{1}\frac{1}{x-a}l_{2}^{\lambda}\frac{1}{x-a}}$$

Integrating, we have, for $a < a^2 < a^3 < a + \delta$,

$$\int_{a}^{a^{*}} \frac{dx}{(x-a)l_{1}\frac{1}{x-a}} \frac{dx}{l_{a}^{*}\frac{1}{x-a}} = \frac{1}{\lambda-1} \left[l_{a}^{*} \frac{1}{a^{\prime\prime}-a} - l_{a}^{1-\lambda} \frac{1}{a^{\prime}-a} \right]$$

< c, for & sufficiently small

Thus the singular integral of |f(x)| at a is evanescent; for

$$\int_{-\infty}^{\infty} |f(x)| dx \le M_0$$

589. Let f(x) be regular in $\mathfrak{A} = (a, b)$ except at a. Let f(x) have one sign σ in $V^*(a)$, where

$$(x-a)l_1\frac{1}{x-a}\cdots l_n\frac{1}{x-a}\cdot \sigma f(x)>M>0.$$

Then

$$J = \int_a^b f dx = \sigma \cdot \infty.$$

From 389, 4), for $s = 1, 2, \dots$, and x > a sufficiently near a,

$$D_x l_{s+1} \frac{1}{x-a} = \frac{-1}{(x-a)l_1 \frac{1}{x-a} \cdots l_s \frac{1}{x-a}}.$$

Integrating,

$$\int_a^c \frac{dx}{(x-a)l_1 \frac{1}{x-a} \cdots l_i \frac{1}{x-a}} = l_{i+1} \frac{c-a}{a-a}, \quad a < \alpha < c < a+\delta.$$

Hence

$$\left| \int_a^c f dx \right| > M l_{s+1} \frac{c-a}{a-a},$$

 $\doteq +\infty$, when $\alpha \doteq a$.

Hence

$$J = \sigma \cdot \infty$$
.

590. The logarithmic tests 588, 589 admit a simple geometric interpretation.

Consider the family of curves

$$C_{s,\lambda}; y = \frac{C}{(x-a)l_1 \frac{1}{x-a} \cdots l_s^{\lambda} \frac{1}{x-a}}, \quad \lambda > 1;$$

and

$$D_{i}; y = \frac{D}{(x-a)l_1 \frac{1}{a} \cdots l_s \frac{1}{a}},$$

in $RI^{T*}(a)$.

It is shown readily that any C curve finally lies constantly below any D curve.

For a given λ , the C curves use as z increases, while the D curves sink as in the figure

The logarithmic tests may now be stated as follows

If |f(x)| finally remains below some C curve f(x) is integrable. On the other hand, if f(x) preserves one sign near a and |f(x)| remains above some D curve, the corresponding integral is infinite.

Properties of Improper Integrals

591 In the following, as heretofore in this chapter, we shall suppose that the integrands have but a finite number of singular points in the intervals considered

When f(x) has more than one singular point in $\mathbb{X} = (a, b)$ we can break \mathbb{X} into partial intervals, such that f(x) has a singular point only at one end of each such interval

For example, if the points $a \in c_1$ c_2 are the singular points of f(x) in X, we have, by 576 577, f being integrable,

$$\int_{a}^{b} f dx = \int_{a}^{b_{1}} + \int_{a_{1}}^{a_{2}} + \int_{a_{1}}^{a_{2}} + \int_{a_{1}}^{a_{2}} + \int_{a_{1}}^{a_{2}} + \int_{a_{1}}^{a_{2}} + \int_{a_{2}}^{a_{2}} + \int_{a_{1}}^{a_{2}} + \int_{a_{2}}^{a_{2}} + \int_{a_{2}}^{$$

where a₁, a₂ are points lying between the singular points

On account of this property we may simplify the form of our demonstration often, by supposing of to have but one singular point, which for convenience we shall take at the lower end of the interval

592 Let $f_1(x)$, $f_a(x)$ be integrable in (a, b) Then

$$\int_{a}^{b} (c_{1}f_{1} + c_{2}f_{2})dx = c_{1}\int_{a}^{b} f_{1}dx + c_{2}\int_{a}^{b} f_{2}dx \qquad ($$

Suppose f. f. limited except at a

Then, if $a < \alpha < b$,

$$\int_{a}^{b} (c_{1}f_{1} + \dots + c_{n}f_{n}) dx = c_{1} \int_{a}^{b} f_{1} dx + \dots + c_{n} \int_{a}^{b} f_{n} dx.$$

Passing to the limit, we have 1).

593. Let f(x) be integrable in (a, b). Then

$$\int_a^b f(x) dx = \int_a^c f dx + \int_c^b f dx, \qquad a < c < b.$$

If c is a singular point of f, the above relation is a matter of definition by 577.

If c is not a singular point, the demonstration follows at once from 576, 577.

594. In $\mathfrak{A} = (a, b)$ let f(x) be integrable, and

 $f(x) \subseteq M$.

Then

$$\int_{a}^{b} f(x) dx = M(b-a), \quad a < b.$$
 (1)

For, suppose a is the only singular point in \mathfrak{A} .

Then, if $a < \alpha < b$,

$$\int_a^b f dx = M(b-a), \text{ by 526, 1.}$$

Passing to the limit $\alpha = a$, we have 1).

595. Let f(x), g(x) be integrable in (a, b). Except possibly at the singular points, let $f(x) \ge g(x)$. Then

$$\int_{a}^{b} f dx \ge \int_{a}^{b} g dx. \tag{1}$$

Suppose f, g are limited except at a.

If $a < \alpha < b$,

$$\int_a^b f dx \ge \int_a^b g dx, \quad \text{by 526, 2.}$$

Passing to the limit $\alpha = a$, we have 1).

596 Let f(x), g(x) be integrable in (a b)

Except possibly at the singular points let $f(x) \ge g(x)$ At a point of continuity c of these functions let $f(x) \ge g(x)$

$$\int_{0}^{x} f dx > \int_{0}^{x} f dx$$
 (1)

Then

(2

Suppose f g are limited except at aLet a < a < c < b Then by 527, 2

$$\int_{a}^{b} f dx > \int_{a}^{b} g dx,$$

by 595,

114

$$\int_{a}^{b} f dx \geq \int_{a}^{b} g dx$$

Adding we have 1)

597 Let f(x) be absolutely integrable in (a, b) Then f(x) is integrable in (a, b) and

$$\left| \int_{a}^{a} f dx \right| \leq \int_{a}^{a} |f(x)| dx \tag{1}$$

In 578 we saw that f(x) is integrable in (a, b) buppose f(x) is limited except at aLet $a < \alpha < b$ Then by 528

on by 528 $\left| \int_{-\infty}^{\infty} f dx \right| \leq \int_{-\infty}^{\infty} |f| dx$

Passing to the limit, we have 1)

Suppose c_1 c_2 c_2 are the singular points. Then, if $c_n < a_n < c_{n+1}$, n = 1, 2, n = 1.

$$\int_{a}^{b} f dx = \int_{a}^{c_{1}} + \int_{c_{1}}^{a} + \int_{c_{2}}^{b} + \int_{c_{3}}^{b}$$

Hence

$$\begin{split} \left| \int_{a}^{s} f dx \right| &\leq \left| \int_{a}^{\infty} \left| + \right| \int_{a}^{\infty} \right| + \\ &\leq \int_{a}^{\infty} |f| dx + \int_{a}^{\infty} |f| dx + \quad , \qquad \text{by 2)}, \end{split}$$

598. Let f(x) be integrable in $\mathfrak{A} = (a, b)$.

Let

$$J = \int_a^b f dx.$$

We may change the values of f(x) over any discrete point aggregate in X without altering the value of J, provided the new values of f are limited.

Suppose f limited except at a. Let $a < \alpha < b$. Then, by 530, 2,

$$\int_a^b f dx = \int_a^b g dx,$$

where g is the new function.

Let now $a \doteq a$. The integral on the left converges to J. Hence

$$\lim_{a=a} \int_a^b g dx = \int_a^b g dx = J.$$

599. 1. Let f(x), g(x) be absolutely integrable in $\mathfrak{A} = (a, b)$, having none of their singular points in common. Then h = fg is absolutely integrable in \mathfrak{A} .

To fix the ideas, let c be a singular point of f, but not of g; a < c < b. Then g is limited and integrable in $V_{\delta}(c)$.

Consider one of the singular integrals of |h(x)| at c; say the right-hand one,

 $R = \int_{\gamma}^{\gamma'} |fg| dx, \qquad c < \gamma' < \gamma'' < c + \delta.$

Let Θ be a mean value of |g(x)| in V(c). Then, by 531,

$$R = \Theta \int_{\cdot}^{\gamma''} |f| dx.$$

But |f(x)| being integrable,

$$\lim_{x\to 0}\int_{\gamma'}^{\gamma''}|f|dx=0.$$

Hence

$$\lim R = 0$$
,

as Θ is less than some positive number M.

416

2 In N = (a b) let f(x) be untegrable and g(x) limited and monotone Then fy is integrable in I For simplicity, suppose f is limited except at b We must show that

 $\epsilon > 0$, $\delta > 0$, $\left| \int_{-\delta}^{a} f g dx \right| < \epsilon$, $\delta - \delta < \epsilon$, $d < \delta$

Now, by the Second Theorem of the Mean, 545,

$$\int_{a}^{4} f g dx = g(c+0) \int_{c}^{\xi} f dx + g(d-0) \int_{\xi}^{d} f dx, \quad c \le \xi \le \delta$$

But f being integrable in M, the integrals on the right are numerically as small as we choose if 5 is chosen sufficiently small

600 If f(x) g(x) have a singular point in common, fg may not be integrable, as the following example shows

$$f(x) = g(x) = \frac{1}{\sqrt{1-x^2}} \qquad \% = (0 \ 1)$$

Here, by 583, f and g are absolutely maggrable in M. On the other hand,

Hence, by 580 2

$$h = f_0 = \frac{1}{1 - x^2}$$

$$\int_0^1 \lambda dx = \int_0^1 \frac{dz}{1-z^2} = + \infty,$$

and h is not interrable in (0-1)

601 Let f(x) be absolutely integrable in $\Re = (a \ b)$ Let g(x) be integrable in A and |g(x)| < G Then fg is integrable in A, and

$$\left| \int_{X} f g dx \right| \le G \int_{\mathbb{R}} |f| dx \tag{1}$$

For, g(x) being limited and integrable, [g(x)] is also integrable, by 507 Hence | fg | is integrable in M, by 599 For simplicity, suppose that b is the only singular point of f(x) Let $a < \beta < b$. Then, by 528, $\left|\int_{-f}^{f} fg dx\right| \leq \int_{-f}^{f} \left|fg\right| dx$

 $\leq G \int |f| dx$, by 529.

Passing to the limit $\beta = \delta$, we get 1).

602. 1. Let f(x) be non-negative and integrable in $\mathfrak{A} = (a, b)$. Let g(x) be integrable, and

$$m < g(x) < M$$
.

Then

$$m \int_{\mathfrak{A}} f dx \le \int_{\mathfrak{A}} f g dx \le M \int_{\mathfrak{A}} f dx; \tag{1}$$

07

$$\int_{\mathfrak{A}} fg dx = G \int_{\mathfrak{A}} f dx, \qquad G = Mean g(x). \quad (2)$$

For, as in 601, fg is integrable. If, to fix the ideas, we suppose b is the only singular point of f, we have, by 529,

$$m \int_{a}^{\beta} f dx \le \int_{a}^{\beta} f g dx \le M \int_{a}^{\beta} f dx, \qquad a < \beta < b,$$

which gives 1) on passing to the limit $\beta = b$.

Equation 2) is obviously only another form of 1).

2. As a corollary we have:

Let f(x) be non-negative and integrable in (a, b); while g(x) is continuous.

Then

$$\int_a^b fg dx = g(\xi) \int_a^b f dx, \qquad a \le \xi \le b.$$

3. By repeating the reasoning of 534 and using 596, we have:

Let f(x) be integrable and non-negative; while g(x) is continuous in \mathfrak{A} . Let c be a point of continuity of f(x), and

 $\operatorname{Min} g(x) < g(c) < \operatorname{Max} g(x), \quad \text{in } \mathfrak{A}.$

Then

$$\int_a^b f g dx = g(\xi) \int_a^b f dx, \qquad a < \xi < b.$$

603. 1. Let f(x) be integrable in $\mathfrak{A} = (a, b)$. Then

$$J(x) = \int_{\alpha}^{x} f dx, \qquad \alpha, x \text{ in } \mathfrak{A},$$

is a continuous function of x in A.

To fix the ideas, let $a \le \alpha < x \le b$.

Then

$$\Delta J = \int_{-\pi}^{x+h} f dx.$$

If f(x) is limited in V(x),

$$\lim_{\longrightarrow} \Delta J = 0 \tag{1}$$

by 536 If x is a singular point, 1) still holds by 574, since f is integrable in $\mathfrak A$

2 As corollary we have

Let f(x) be integrable in (a b) Then

$$\lim \int_a^x f(x)dx = \int_a^b f(x)dx, \quad a < x < b$$

604 1 Let f(x) be integrable in $\mathfrak{A}=(ab)$ If f(x) is continuous at x, $\frac{d}{dx}\int_{-\infty}^{x} fdx = f(x) \qquad a, x \text{ in } \mathfrak{A}.$

To fix the ideas let $a \le a < x < b$ Since f is continuous at x, this is not a singular point of f Let e be chosen so that a < e < x, while (a, x) contains no singular point. Then setting

$$J = \int_0^x$$
, $C = \int_0^x$, $K = \int_0^x$

we have J = C + K But, by 537,

$$\frac{dK}{dx} = f(x)$$

Hence, since C is a constant,

$$\frac{dJ}{dx} = \frac{d}{dx}(C+K) = \frac{dK}{dx} = f(z)$$

2 Let f(x) be integrable in $\mathbb{X} = (a \ b)$ If f is continuous at x,

$$\lim_{k\to 0}\frac{1}{k}\int_x^{x+k}f(x)dx = f(x), \qquad x \text{ in } \mathbb{X}$$

This is a corollary of 1

605 In $\mathfrak{A} = (a \ b)$ let f(x) be integrable. Let it be continuous except at certain points e_1 . e_p where f(x) may be unlimited

If F(x) is a one-valued continuous function in \mathfrak{A} , having f(x) as derivative, except at the points c,

$$\int_{a}^{b} f(x)dx = F(b) - F(a). \tag{1}$$

Suppose f(x) is continuous except at a.

Let a < a < b. Then, by 538,

$$\int_{a}^{b} f dx = F(b) - F(\alpha). \tag{2}$$

Since F is continuous,

$$\lim_{\alpha=a} F(\alpha) = F(\alpha).$$

Passing to the limit in 2), we get 1).

Suppose now a and c are points at which f is discontinuous. To fix the ideas, let $a < \alpha < c < b$.

Then

$$\int_{a}^{b} = \int_{a}^{a} + \int_{a}^{c} + \int_{c}^{b} \tag{3}$$

Now as just shown,

$$\int_a^a = F(a) - F(a),$$

$$\int_a^c = F(c) - F(a),$$

$$\int_a^b = F(b) - F(c).$$

Adding, we have 1) from 3).

Ex. 1.

$$\int_{-1}^{1} \frac{dx}{\sqrt{1-x^2}} = \left[\arcsin x\right]_{-1}^{1} = \pi.$$

Here

$$f(x) = \frac{1}{\sqrt{1-x^2}}$$

is integrable in $\mathfrak{A}=(-1,1)$. Its points of discontinuity in \mathfrak{A} are $x=\pm 1$.

$$F(x) = \arcsin x$$

is one-valued and continuous in \mathfrak{A} , and has f(x) as derivative.

Ex. 2. $\int_{1}^{1} \frac{dx}{x^2} = \left[-\frac{1}{x} \right]_{-1}^{1} = -2.$

This result is obviously false, since the integrand is positive. The integrand is not an integrable function in (-1, 1), by 580.

Change of Variable

606 1 Let f(x) be in general regular in $\mathfrak{A} = (a, b)$ $a \leq b$ Let

$$u = \phi(x)$$

have a continuous derivative $\phi'(x) \neq 0$, in A Let $\mathfrak{D} = (\alpha, \beta)$ be the smage of A and let

$$x = \psi(u)$$

be the inverse function of & If either

$$J_x = \int_{\mathbb{R}} f(x)dx$$
 or $J_x = \int_{\mathbb{R}} f[\psi(u)]\psi'(u)du$

is convergent the other is and $J_* = J_*$

By hypothesis the points of M. El stand in I to I correspondence To fix the ideas, let f be regular except at a Let e, q be corre-

sponding points in A B Then by 543, $\int f(x)dx = \int f[\psi(u)]\psi'(u)du,$ a

since
$$f(x)$$
 is limited and integrable in (c, b) . If now $c=a, \gamma=a$, and conversely. Thus if either integral J , or J , is convergent.

and conversely Thus if either integral J, or J, is convergent, the relation 1) shows that the other is, and both are equal In B = (a, β) a ≤ β, let x = ψ(u) have a continuous derivative

which may canish over a discrete aggregate but otherwise has one ngn Let A = (a b) be the image of B Let f(x) be in general regular in A If either

$$J_x = \int_{\mathbb{R}} f(x)dx$$
, or $J_a = \int_{\mathbb{R}} f[\psi(u)]\psi'(u)du$

is convergent the other is and $J_s = J_s$

We employ the reasoning of 1, with the aid of 544

607 Ex L

$$J_a \simeq \int_0^1 \frac{dz}{\sqrt{1-z^2}}$$

Let z = x n u = v(u)

Here ψ' is positive in $B = (0, \pi/2)$ except at $\pi/2$.

Also

$$J_u = \int_0^{\pi/2} du = \frac{\pi}{2}.$$

Obviously J_u is convergent. Hence, by 606, 2,

$$J_z = \pi/2$$

a result already obtained.

Ex. 2.

$$J_z = \int_0^1 \frac{dx}{\sqrt{(1-x^2)(1-\kappa^2x^2)}}, \qquad \kappa^2 < 1.$$

Let

 $x = \sin u$.

Then

$$J_{u} = \int_{0}^{\pi} \frac{du}{\sqrt{1 - \kappa^2 \sin^2 u}}.$$

But the integrand of J_u is continuous in $(0, \pi/2) = \mathfrak{B}$. Hence J_u is finite. Therefore J_z is.

Both these examples illustrate how, by a change of variable, an improper integral may be transformed into a proper integral.

Second Theorem of the Mean

608. Let f(x) be integrable in $\mathfrak{A} = (a, b)$. Let g(x) be limited and monotone in \mathfrak{A} . Then

$$J = \int_{a}^{b} f g dx = g(a+0) \int_{a}^{t} f dx + g(b-0) \int_{t}^{b} f dx,$$
 (1)

where

$$a \leq \xi \leq b$$
.

We assume that g(a + 0), g(b - 0) are different, as otherwise 1) is obviously true.

Let us suppose first, that f is regular in $\mathfrak A$ except at a. Then, by 545, 11), a < a < b

$$\int_{a}^{b} fy dx = g(a+0) \int_{a}^{b} f dx + o(a) \cdot \{g, b-0\} - g(a+0)\}, \quad (2$$

where $\vartheta(\alpha)$ is a mean value of

$$\int_{-\pi}^{b} f dx, \qquad a \le x \le b. \tag{3}$$

In 2) let a=a We have

$$\lim g(a+0)=g(a+0),$$

$$\lim \int f dz = \int f dx$$

As all the terms in 2) except s(a) have a finite limit, it follows that s(a) must have a finite limit s. Hence

$$\int_{a}^{b} f y dx = g(a+0) \int_{a}^{b} f dx + s \{g(b-0) - g(a+0)\}$$
 (4)

Reasoning now as we did at the close of 545, we arrive at equation 1)

Suppose next, that f is regular in $\mathfrak A$ except at a, b. Then if

$$\alpha < \beta < \delta,$$

$$\int_{0}^{\alpha} fg dx = g(\alpha + 0) \int_{0}^{\alpha} fdx + \sigma_{1}(\beta) \{g(\beta - 0) - g(\alpha + 0)\},$$

as we have just seen in 3)
Passing to the limit, we have, as before.

$$\int_{0}^{a} f g dz = g(a+0) \int_{0}^{a} f dx + \delta_{0} \{g(b-0) - g(a+0)\}.$$

This may be transformed as before, giving 1) also for this case. Let us suppose finally, that the singular points of f are

Then

$$J = \int_{a}^{c_1} c_2 \qquad c_a$$

$$J = \int_{a}^{c_1} + \int_{c_1}^{c_2} c_1 + \cdots + \int_{c_n}^{c_n} c_n + \cdots + \int_{c_n$$

If a or b are singular points, the first or last integral may be discarded

By the preceding,

$$\int_{a}^{a} = g(a+0) \int_{a}^{b} f dx + g(e_{1}-0) \int_{e_{1}}^{a} f dx$$

$$= g(a+0) \left\{ \int_{a}^{a} - \int_{e_{1}}^{a} \right\} + g(e_{1}-0) \left\{ \int_{e_{1}}^{a} - \int_{a}^{a} \right\}.$$

Similarly,

Adding all these equations, we get, setting $c_0 = a$, $c_{s+1} = b$:

$$J = g(a+0) \int_{a}^{b} + \sum_{\kappa=1}^{s} \left\{ g(c_{\kappa}+0) - g(c_{\kappa}-0) \right\} \int_{c_{\kappa}}^{b} + \sum_{\kappa=0}^{s} \left\{ g(c_{\kappa+1}-0) - g(c_{\kappa}+0) \right\} \int_{c_{\kappa}}^{b} = g(a+0) \int_{a}^{b} + S + T.$$
 (5)

Now m, M denoting the extremes of the integral 3),

$$\mathfrak{m} \stackrel{!}{\Sigma} \{ g(c_{\kappa} + 0) - g(c_{\kappa} - 0) \} \leq S \leq \mathfrak{M} \Sigma \{ g(c_{\kappa} + 0) - g(c_{\kappa} - 0) \}
\mathfrak{m} \stackrel{!}{\Sigma} \{ g(c_{\kappa+1} - 0) - g(c_{\kappa} + 0) \} \leq T \leq \mathfrak{M} \Sigma \{ g(c_{\kappa+1} - 0) - g(c_{\kappa} + 0) \}.$$

Which added give

$$\mathfrak{m}(g(b-0)-g(a+0)) \leq S+T \leq \mathfrak{M}(g(b-0)-g(a+0)).$$

Thus 5) gives

$$J = g(a+0) \int_a^b + \vartheta(g(b-0) - g(a+0)).$$

This is an equation of the same form as 4). Thus reasoning as we did on 4), we get 1).

INTEGRALS DEPENDING ON A PAHAMETER

Umform Convergence

609 Let f(x, y) be defined over a rectangle $R = (a, b, \alpha, \beta), \beta$ finite or infinite, and be unlimited in R Let $\mathfrak{A}=(a,b)$, $\mathfrak{B}=(a,\beta)$ For each win B. let

 $J(y) = \int_{-1}^{1} f(x, y) dx$

be convergent Then J is a one valued function of y in B

As in Chapter XIII, we wish now to study J with respect to continuity differentiation, and integration, restricting ourselves to certain simple but important cases

- 610 1 For brevity we introduce the following terms shall say f(xy) is regular in R = (abag) & finite or infinite, when
 - 1º f(xy) has no points of infinite discontinuity in R
 - 2º f(xy) is integrable in $\Re = (a \ b)$ for each y in $\Re = (a, B)$
- When B is finite, we shall sometimes need to integrate f(xy) with respect to y In this case we shall also suppose
 - 8° f(xv) is integrable in H = (a, B) for each x in A

For example $f(x, y) = y \sin x$ is regular in R If β is finite f is l anised in R If $\beta = \infty$, f is not limited in R although it has so points of infinite discontinuity

- 2 If f(zy) is regular in R except that it may have points of infinite discontinuity on certain lines -= a, x=a, we shall say f(xy) is regular in R except on the lines x = a. . or that it is in general regular with respect to x
 - 3 Let f(xy) be continuous in R except on certain lines

$$x = \alpha_1$$
 $x = \alpha_r$ $y = \alpha_1$, $y = \alpha_r$

On the lines $x = a_1$ it may have points of infinite discontinuity, on the lines y = a, it may have finite discontinuities is otherwise regular, e shall say it is simply regular except on the lines $x = a_1$, $x = a_1$, $y = a_1$, $y = a_2$, or that it is simply irregular lar with respect to a

Thus the simply stregular functions are a special case of the functions which are in general regular

4. The lines $x = a_1, \dots x = a_r$, on which f(xy) may have points of infinite discontinuity are called singular lines.

The integrals

$$\int_{a_{\iota}-\delta}^{a_{\iota}} f dx, \quad \int_{a_{\iota}}^{a_{\iota}+\delta} f dx \quad \delta > 0, \text{ arbitrarily small}$$

are called the left and right hand singular integrals relative to the lines $x = a_i$, $i = 1, 2 \cdots r$.

5. In 609 we made the formal requirement that f(xy) should be defined at every point of R. It usually happens in practice that f is not defined at its points of infinite discontinuity. Such is the case in such integrals as

$$\int \frac{dx}{\sqrt{xy}}, \quad \int \frac{y^2 - x^2}{(x^2 + y^2)^2} dx, \quad \int x^{y-1} \log^n x \, dx.$$

It is, however, easy to satisfy the above requirement in all the cases we shall consider; for, by 598, the value of

$$\int_a^b f(x, y) dx$$

is not affected by a change of the value of f at points lying on the lines $x = a_1 \cdots$ subject to the restrictions of that theorem.

- 6. This fact may also be used to advantage sometimes to simplify f(x, y) by changing its value at points lying on these lines.
- 611. 1. Let f(xy) be regular in $R = (ab\alpha\beta)$, β finite or infinite, except on $x = a_1, \cdots$

If the singular integrals relative to these lines be uniformly evanescent in B, we say

$$J = \int_a^b f(x, y) dx$$

is uniformly convergent in B.

- 2. If J is uniformly convergent in the intervals $\mathfrak{B}_1, \dots \mathfrak{B}_m$, it is obviously uniformly convergent in their sum.
- 3. If J is the sum of several uniformly convergent integrals in \mathfrak{B} , it is itself uniformly convergent in \mathfrak{B} .

4 Let f(xy) be in general regular with respect to x in $R = (aba\beta)$, β finite If J is uniformly convergent in $\mathfrak B$ it is similar in $\mathfrak B$. For simplicity suppose x = b is the only singular line. Then

But in the rectangle (ab'aß),

Now

426

$$J = \int_{a}^{u} + \int_{v}^{b}$$

$$|J| < M(b-a) + \sigma$$

612 Let f(xy) be regular in $R = (aba\beta)$, β finite or infinite,

except on x = b

The singular sitegral
$$\int_{b}^{b} f(xy) dx, \quad b_{0} \leq b' < b,$$
 (1)

is uniformly evanescent in B = (a B) if

$$|f(xy)| \le \phi(x)$$
, in $\mathfrak{A}' = (\delta_0, \delta)$,

and φ ss sntegrable sn Ν'

For, f(xy) being limited and integrable in (b', b''), where b' < b'' < b, we have for any y in $\mathfrak B$

$$\left| \int_{a}^{b} f dx \right| \leq \int_{a}^{b} |f| dx, \text{ by } 528$$

$$\leq \int_{a}^{b} \phi dx, \text{ by } 526, 2$$

But ϕ being integrable in $\mathfrak A$ we can take δ_0 so near δ that the last integral is $<\epsilon$ But as this is independent of y,

Hence 1) is uniformly evanescent.

613. Example. Let us consider the integral

$$J = \int_0^{\pi} \log (1 - 2y \cos x + y^2) dx$$
 (1)

for values of y in $\mathfrak{B} = (\alpha, \beta)$, β finite. The integrand f(xy) is continuous except at the points

 $x = m\pi$, $y = (-1)^m$, $m = 0, \pm 1, \cdots$

by 560, Ex. 2. Let us first consider the singular integral

$$S = \int_0^{a'} f dx, \qquad 0 < a' < \delta$$

relative to the line x = 0. Since y = 1 is the only point of infinite discontinuity on this line, we may restrict ourselves to an interval $\mathfrak{B}' = (1 - \sigma, 1 + \sigma)$. We set

$$y=1+h, \quad |h| \leq \sigma.$$

Then

$$S = \int_0^a \log \left\{ 2(1+h)\left(1-\cos x + \frac{h^2}{2(1+h)}\right) \right\} dx$$

$$= \log 2(1+h)\int_0^a dx + \int_0^a \log\left(1-\cos x + \frac{h^2}{2(1+h)}\right) dx$$

$$= S_1 + S_2.$$

Obviously S_1 is uniformly evanescent in \mathfrak{B}' .

To show that S_2 is uniformly evanescent, we observe that

$$\left|\log\left(1-\cos x+\frac{h^2}{2(1+h)}\right)\right|\leq |\log\left(1-\cos x\right)|,$$

since $\log x$ increases with x, and is negative for small values of the argument. We apply now 612. To this end we show that

$$\phi(x) = \log\left(1 - \cos x\right)$$

is absolutely integrable in (0, a'), using the μ -test.

Now in 454, Ex. 1, we saw that

$$R \lim_{n \to 0} x^{\mu} \log (1 - \cos x) = 0, \quad 0 < \mu < 1.$$

Hence $|\phi|$ is integrable, and S_2 is uniformly evanescent. Hence S is uniformly evanescent not only in \mathfrak{B}' , but in \mathfrak{B} .

The same reasoning may be applied to the singular integral relative to the line z=r. Here the only point of infinite discontinuity is y=-1.

Hence, by 611, 2, the integral J is uniformly convergent in B.

428

614. Example Let us consider the integral

$$J = \int_0^1 x^{n-1} \{\log x\}^{-1} x, \quad n \leq 0.$$

We show first that it is convergent only for y>0

For, let y>0 Applying the a text, we have

$$\lim_{x\to\infty} |x^{n-1}| \log x|^n = \lim_x x^n |\log x|^n$$

for properly chosen 0<#<1

Hence, by 679 J is convergent.

$$=0$$
, by 454, Ex. 2,
 $\mu < 1$
convergent.
 $\lim_{n \to \infty} \frac{\pi^n}{2^n} = \lim_{n \to \infty} \frac{\pi^n}{2^n} = \frac{\pi^n}{2^n}$

Hence, by 350 J is divergent.

Let $0 < \alpha < \beta$ We show that J is uniformly convergent in $\mathfrak{B} \approx (\alpha, \beta)$. In the

first place we note that the integrand is continuous in $R=(0.1 \pm a, 9)$ except on the line x=0 where it has points of infinite discontinuity. We have therefore only to show that the enginear integral S relative to this line is uniformly evantament. To this end we use 612. Now

$$xr^{-1}|\log x|^{\alpha} < r^{\alpha}$$
 if $\log x(r^{\alpha} + r^{\alpha})$. But we have just seen that

 $\phi(x) = x^{n-1} \{ \log x \}^n$ is a tegrable Hence B is antiounly evanescent in \mathfrak{B}

a

615 Let f(xy) be regular in $R = (aba\beta)_1 \beta$ finite or infinite, except on x = b. The singular integral

$$\int_b^b f(xy)dx, \quad b' < b,$$

is uniformly evanescent in B = (a \beta), if

$$f(xy) = \phi(x)g(xy)$$
, on $R_b = (b - \delta, b, \alpha, \beta)$,

where $1^a \phi(x)$ is integrable in $\mathcal{U} = (b - \delta, b)$,

2° g(xy) is limited in R_b and integrable in any $(b-\delta, b'')$, b'' < b, for each y in \mathfrak{B}

For, by 2° , |g(xy)| < M

Then by 1°, there exist for each $\epsilon > 0$, $\epsilon > 0$ such that

$$\left|\int_{s}^{s} \phi(x)dx\right| < \frac{\epsilon}{M} \tag{1}$$

Then for any y in \mathfrak{B} ,

$$\begin{aligned} \left| \int_{b^{*}}^{b^{*}} f dx \right| &= \left| \int_{b^{*}}^{b^{*}} \phi g dx \right| \\ &< M \left| \int_{b^{*}}^{b^{*}} \phi dx \right| \\ &\le \epsilon, \text{ by 1).} \end{aligned}$$

Continuity

616. 1. Let f(xy) be regular in $R = (ab\alpha\beta)$, β finite or infinite, except on the lines $x = a_1, \dots x = a_r$.

1°. Let the singular integrals relative to these lines be uniformly evanescent in $\mathfrak{B} = (\alpha, \beta)$.

2°. Let η, finite or infinite, lie in B, and

$$\lim_{x \to \infty} f(xy) = \phi(x) \qquad uniformly$$

in $\mathfrak{A} = (a, b)$, except possibly at $x = a_1, \dots x = a_r$.

3°. Let $\phi(x)$ be integrable in \mathfrak{A} . Then

$$\lim_{x \to \eta} \int_a^b f(xy) dx = \int_a^b \lim_{x \to \eta} f(xy) dx = \int_a^b \phi(x) dx. \tag{1}$$

For simplicity, we shall suppose there is only one singular line, viz. x = b; we shall also take $\eta = \infty$.

Let

$$D = \int_a^b \{f(xy) - \phi(x)\} dx.$$

We wish to show that

$$\epsilon > 0$$
, G , $|D| < \epsilon$, for any $y > G$.

Now

$$\begin{split} D &= \int_{\delta}^{b} \{f(xy) - \phi(x)\} dx + \int_{b}^{b} f dx - \int_{b}^{b} \phi dx, \qquad b' < b, \\ &= D_1 + D_2 + D_2. \end{split}$$

Now by 1°, 3°, the last two integrals are numerically $< \epsilon/3$, if b' is sufficiently near b, for any y On the other hand, if G is sufficiently large, we have for any y>G,

$$|f(xy)-\phi(x)|<\frac{\epsilon}{3(b-a)},$$

for every x in (a b'), by virtue of 2°
Hence | D₁| < \epsilon / 3 Hence

$$|D| < \epsilon$$
, $y > G$,

which establishes 1) $|D| < \epsilon, y > \epsilon$

- 2 Let f(xy) be regular in $R=(aba\beta)$, β finite or infinite, except on the lines $x=a_1, \quad x=a_r$
- 1° Let the singular integrals relative to these lines be uniformly evanescent in $\mathfrak{B} = (a,\beta)$
 - 2º Let η, finite or infinite, lie in B and

$$\lim_{x \to a} f(x, y) = \phi(x) \qquad uniformly$$

in A = (ab), except possibly at $x = a_1$ $x = a_2$.

Then

$$j = \lim_{x \to 0} \int_{x}^{b} f(xy) dx$$
 exists

3° Let φ(x) be integrable in A Then

$$\lim_{x \to \infty} \int_{a}^{b} f(xy) dx = \int_{a}^{b} \lim_{x \to \infty} f(xy) dx = \int_{a}^{b} \phi(x) dx$$

We need only show that y exists, since the rest follows by 1 Let us suppose, to fix the ideas, that x=b is the only singular line, and that $y=\infty$

Then $D = \int_{-1}^{1} \{f(x, y') - f(x, y'')\} dx$

$$= \int_{a}^{b} \{f(x, y') - f(x, y'')\} dx + \int_{a}^{b} f(x, y') dx - \int_{a}^{b} f(x, y'') dx$$

$$= D_{a} + D_{a} + D_{a}$$

But by 1°, there exists a b' such that

$$|D_2|$$
, $|D_3| < \epsilon/4$

for any y in B.

By 2°, we can take γ such that for any x in (a, b')

$$|f(xy)-\phi(x)|<\frac{\epsilon}{4(b-a)}, \quad y>\gamma.$$

Hence

$$|f(x, y')-f(x, y'')|<\frac{\epsilon}{2(b-a)},$$

for any y', $y'' > \gamma$, and x in (a, b').

Thus

$$|D_1| < \epsilon/2$$
.

Hence

$$|D| < \epsilon$$
, for any $y > \gamma$;

and the limit j exists.

617. 1. In 561 we have defined the term f(x, y) as a uniformly continuous function of y in \mathfrak{B} . It may happen that f(x, y+h) converges to f(xy) for each y in \mathfrak{B} and any x in \mathfrak{A} , but that the uniform convergence breaks down at points lying on the lines $x = a_1, \dots x = a_r$. In this ease, we shall say f is a regularly continuous function of y in \mathfrak{B} . If f(x, y+h) converges uniformly to f(xy) except on $x = a_1, \dots$, where it may not even converge to f(x, y), we shall say that f(xy) is a semi-uniformly continuous function of y.

In both cases, we can inclose the lines $x = a_1, \cdots$ in little bands of width small at pleasure but fixed, such that the convergence is uniform in \mathfrak{B} , when x ranges over \mathfrak{A} , excluding values which fall in the above bands.

- 2. It may happen that f(x, y) is a regularly or a semi-uniformly continuous function of y in \mathfrak{B} except on the lines $y = \alpha_1, \dots y = \alpha_s$. We shall say in this case that f is in general regularly or semi-uniformly continuous in y.
- 3. We wish to make a remark here which will sometimes permit us to simplify the form of a demonstration without loss of generality. In questions of uniform convergence or uniform continuity, the uniformity may break down at points lying on certain lines $x = a_1, \dots x = a_m$. In this case we may count such lines as

singular lines. When \$\beta\$ is finite, and no points of infinite discontinuity lie on these lines, their singular integrals are obviously uniformly evanescent in \$\mathfrak{G}\$

618 1 As corollaries of 616 we have using 611, 4

Let f(xy) be an general regular with respect to x in $R = (aba\beta)$, β finite

Let f(xy) be a semi uniformly continuous function of y, except at y = a, y = a

 $J(z) = \int_{z}^{z} f(xy)dx \qquad (1)$

be uniformly convergent in $\mathfrak{B} = (a\beta)$

Then I is limited in B and continuous, except possibly at at

2 Let f(xy) be continuous in R except on $x=a_1$ $x=a_r$ Let 1) be unifornly convergent in $\mathfrak B$ Then J is continuous in $\mathfrak B$

619 Ex 1 The integral

432

Tet.

$$J = \int_0^y \log (1 - 2y \cos x + y^4) dx$$

is a continuous funct on of y in any interval $\mathfrak{B} \sim (0.5)$ For the integrand is continuous in $(0 \times \alpha)$ except on the lines x = 0 x = x is 613 we saw J is uniformly convergent in \mathfrak{D} . Hence, by 618, 2. J is continuous

Ex. 2 The integral $J = \int_{-2\pi}^{\pi} z_1 \log y i^n dx$

is continuous in $(n \beta)$ 0 < $\alpha < \beta$ This follows from 618 2 and 614

Integration

620 1 Up to the present we have been considering the case when the singular integrals

$$S \approx \int_{-\infty}^{\infty} f(xy)dx$$

relative to a line x = c are uniformly evanescent

For the purpose of integrating

$$J(y) = \int_a^b f(xy) dx$$

with respect to the parameter y over a finite interval $\mathfrak{B} = (\alpha, \beta)$, we can take a slightly more general case.

As before, let f(xy) be in general regular in $R = (ab\alpha\beta)$. To fix the ideas, let us consider the left-hand singular integral at c.

Suppose now that for each $\epsilon > 0$ there exists a $\delta > 0$ such that for any y in $\mathfrak{B}^* = (\alpha, \beta^*)$,

$$|S_c| \leq \epsilon \sigma(y)$$

for every c' in $(c - \delta, c)$. Here σ is regular in \mathfrak{B} except at β , and is integrable in \mathfrak{B} ; it is also independent of ϵ . In this case we shall say this singular integral is *normal*. Similar remarks hold for the right-hand singular integral at c.

2. Obviously, if the singular integrals at c are normal, they are uniformly evanescent in any partial interval $(\alpha\beta^{l})$ of \mathfrak{B} .

Also, if the singular integrals at c are uniformly evanescent in \mathfrak{B} , they are a fortiori normal.

3. When the singular integrals of

$$J = \int_{a}^{b} f(xy) dx$$

are normal, we shall say J is normally convergent in \mathfrak{B} .

4. If the singular integrals at c are normal, there exists for each $\epsilon > 0$, a $\delta > 0$, such that

 $\left|\int_{\lambda}^{\mu} dy \int_{c}^{c} f dx\right| \leq \epsilon,$

for any c' in $(c - \delta, c)$ or $(c, c + \delta)$, and any λ , μ in \mathfrak{B} .

To fix the ideas consider only the left-hand singular integral.

Then

$$\left| \int_{c}^{c} f dx \right| < \frac{\epsilon \sigma(y)}{S},$$

where

$$S = \int_{\alpha}^{\beta} \sigma dy = \int_{\lambda}^{\mu} \sigma dy.$$

Hence

$$\left|\int_{\lambda}^{\mu} \int_{c'}^{c} \left| \leq \int_{\lambda}^{\mu} \left| \int_{c'}^{c} \left| \leq \frac{\varepsilon}{S} \int_{\lambda}^{\mu} \leq \varepsilon. \right| \right| \right|$$

621 Let f(xy) be an general regular with respect to x, in R = (abaB), B finite

1º Let f be in general a semi-uniformly continuous function of $y : n \mathfrak{B} \simeq (\alpha, \beta)$

 $J(y) = \int_{-1}^{1} f(xy) dx$ 2º Let

be normally convergent an B

Then J is integrable in B

To fix the ideas let z = 6 be the only singular line Since the singular integral is normal in B, it is uniformly evanescent in any (αγ), γ < β, by 620, 2 Hence, by

618, 1, J is integrable in (a, y)

To show that J is integrable in

To show that
$$J$$
 is principable in β , we have only to show that
$$T = \int_{\sigma}^{T} J dy,$$

$$\beta - \eta < \beta' < \beta'' < \beta,$$

converges to 2 as n = 0

Now
$$T = \int_{x}^{x} dy \int_{0}^{x} f dx = \int_{x}^{y} \int_{0}^{y} + \int_{0}^{y} \int_{y}^{x} = T_{1} + T_{2}$$
 (1)

But, by 620, 4, there exists a b' such that

however
$$S'$$
, S' are chosen $|T_3| < \epsilon/2$, $\delta' < \delta$,

On the other hand, f(xy) being by hypothesis limited in any

(a, b, n, B), b' < b

$$\left|\int_{a}^{x} f dx\right| < M$$

We can therefore choose a so small that $|T_1| < \epsilon/2$

Hence 1) shows that for each $\epsilon > 0$, there exists an $\eta > 0$, such that |T| < e

for any pair of values $\beta'\beta''$ in $(\beta - n, \beta^*)$

Inversion

622. 1. Let f(xy) be in general regular with respect to x, in $R = (aba\beta)$.

1°. Let the singular integrals be normal.

2°. Let f(xy) be in general a semi-uniformly continuous function of y in \mathfrak{B} .

 3° . Let inversion of the order of integration be permissible for any rectangle in R not embracing the singular lines.

Then

$$K = \int_a^\beta dy \int_a^b f dx, \qquad L = \int_a^b dx \int_a^\beta f dy$$

exist, and are equal.

For simplicity, let us suppose x = b is the only singular line.

By 1°, 2°, and 621, the integral K exists.

By 3°

$$\int_{a}^{\beta} dy \int_{a}^{b'} f dx = \int_{a}^{b'} dx \int_{a}^{\beta} f dy. \qquad b - \delta < b' < b. \quad (1)$$

But

$$\int_{a}^{\beta} \int_{a}^{b'} = \int_{a}^{\beta} \int_{a}^{b} - \int_{a}^{\beta} \int_{b'}^{b}, \quad \text{since } K \text{ exists,}$$

$$=K-\int_a^\beta \int_{b'}^b.$$
 (2)

Hence 1), 2) give

$$\left| \int_{a}^{b} \int_{a}^{\beta} - K \right| = \left| \int_{a}^{\beta} \int_{b'}^{b} \right|$$

$$< \epsilon, \quad \text{by 620, 4}$$

if δ is taken sufficiently small.

Now, by 603, 2,

$$\int_a^b \int_a^\beta = \lim_{b' \to b} \int_a^b \int_a^\beta.$$

Hence, by 3),

$$L = \int_a^b \int_a^\beta = K.$$

2. Let f(xy) be simply irregular in $R = (ab\alpha\beta)$ with respect to x Let the singular integrals be normal. Then

$$\int_a^\beta dy \int_a^b f dx, \quad \int_a^b dx \int_a^\beta f dy$$

exist and are equal.

This is a special case of 1 For by 617, 3, f is in general a regularly continuous function of g Thus condition 2" is satisfied That condition 3° is fulfilled follows from 570, 1

623 Example We saw 575 Ex 3 that

п

Hence for
$$0 < \alpha < \beta$$

$$\int_{a}^{b} dy \int_{a}^{1} x^{y} dx - \int_{a}^{b} \frac{dy}{y} - \log \frac{\beta}{\alpha}$$

We can by 622 2 invertable order of integration a nee-

is uniformly evanescent in (a \$) by 614 Thus 1) gives, inverting

$$\log \frac{\beta}{r} = \int_{0}^{1} dz \int_{0}^{2\pi} z^{2} dz = \int_{0}^{1} \frac{z^{2}}{r^{2}} \frac{1-z^{2}}{r^{2}} dz.$$
 (2)

For a = 1 this gives

$$\int_0^1 \frac{2^{\beta-1}-1}{\log x} dx = \log \beta$$
(3)

If we get here $\beta = 2$ is given

$$\int_{0}^{\infty} \frac{x-1}{\log x} dx = \log 2 \tag{6}$$

624 We give now an example where it is not permitted to invert the order of integration

We have for all points differer a from the or gun

$$D_k \frac{x}{x^2 + y^2} - \frac{y^2 - x^2}{(x^2 + y^2)^2}$$

 $D_i = \frac{y}{x^2 + x^4} - \frac{x^2 + y^4}{(x^4 + y^4)^4}$

$$\begin{split} A &\simeq \int_0^1 dy \int_0^1 \frac{y^2 - z^2}{(x^2 + y^2)^2} dx = \int_0^1 dy \left[\frac{x}{x^2 + y^2} \right]_0^1 = \int_0^1 \frac{dy}{1 + y^2} = \frac{x}{4}, \\ B &= \int_0^1 dx \int_0^1 \frac{y^2 - z^2}{(x^2 + x)^2} dy = -\int_0^1 dz \left[\frac{y}{x^2 + y^2} \right]_0^1 = -\int_0^1 \frac{dz}{1 + x^2} \simeq -\frac{x}{4}. \end{split}$$

Hence A, B are both convergent but they are not equal

625. 1. Up to the present we have supposed that the points of infinite discontinuity of the integrand f(xy) lie on certain lines parallel to the y-axis.

We consider now a more general case.

Let us suppose that these points of infinite discontinuity do not lie only on a finite number of lines parallel to the y-axis, but that it is necessary to employ in addition a finite number of lines parallel to the x-axis.

To fix the ideas, let these lines be

$$x = a_1, \cdots x = a_r; \quad y = a_1, \cdots y = a_r.$$
 (1)

If f(xy) is otherwise regular, i.e. if properties 2°, 3° of 610, 1 hold, we shall say f(xy) is regular in R except on the lines 1), or that it is in general regular with respect to x, y.

- 2. Similarly we extend the term simply regular, viz.: If f(xy) is continuous in R except on a finite number of lines parallel to each axis, say the lines 1), where it may have points of finite or infinite discontinuity; if, moreover, it cujoys properties 2° , 3° of 610, 1, we shall say f(xy) is simply regular in R except on the lines 1), or that it is simply irregular with respect to x, y.
- 3. The lines $y = \alpha_1$, ... are also called singular lines, and the integrals

$$\int_{a}^{a} f dy$$

are singular integrals relative to the lines $y = \alpha_m$, $m = 1, 2 \cdots s$.

4. In accordance with the present assumptions, we should modify the definition of normal singular integrals given in 620, 1, so as to allow $\sigma(y)$ to have singular points at $\alpha_1, \dots \alpha_s$.

As an example, consider

$$f(xy) = \frac{1}{\sqrt{(x-b)(y-\beta)}}$$

Here every point on the lines x = b, $y = \beta$ are points of infinite discontinuity. If $R = (a, b, \alpha, \beta)$, a < b, $\alpha < \beta$, we see at once that f is continuous in R except on the above lines. Obviously, f is integrable with respect to x or y in R. Thus f is simply regular in R except on the lines x = b, $y = \beta$.

626 1 Let f(xy) be regular in R = (aba\$), except on the lines

 $x = a_1, \quad x = a_r, \quad y = a_1$ $y = \alpha_c$ 1º Let it be in general a semi uniformly continuous function of y

in 2 = (aB)

2º Let the singular integrals relative to the lines x = a, he normal in A

3° Let the singular integrals relative to the lines $y = a_1$, be uniformly evanescent in any interval of H = (ab), not embracing the points a, a,

4º Let any integral fdy fdz

admit inversion if the rectangle (a'b'a'B') does not embrace one of the singular lines Then

 $J(y) = \int_{-x}^{x} f(x, y) dx$

18 integrable in B

438

For simplicity, let us assume that there is only one singular line x = b and one has $y = \beta$

We observe, first, that J is integrable in any $(\alpha B')$, B' < B by 1°, 2°, and 620, 2, 621 Therefore, to show that J is integrable in \$9, it suffices to prove that, for each \$\epsilon 0\$ there exists an \$n > 0\$, such that

$$T = \int_{0}^{\pi} J dy$$

is numerically $<\epsilon$ for any pair of numbers $\beta'\beta''$ in $\mathbb{C}=(\beta-n,\beta)$ Now

 $T = \int_{a}^{a} dy \int_{a}^{b} f dx = \int_{a}^{a} \int_{a}^{b} \int_{a}^{b} \int_{a}^{b} T_{1} + T_{2}$ (1

But by 2° and 620, 4,

T21<e/2

if b' is taken sufficiently near b Suppose b' so chosen and then fixed

On account of 4°. $T_1 = \int_0^a \int_a^a$

By virtue of 3" we can take n > 0 sufficiently small so that

$$\left|\int_a^b f dy\right| < \frac{\epsilon}{9(h-a)} \quad \text{in } (a\ b')$$

Hence

 $|T_1| < \epsilon/2$.

Therefore

 $|T| < \epsilon$, for any $\beta' \beta''$ in \mathfrak{C} .

- 2. Let f(xy) be simply regular in $R = (ab\alpha\beta)$, except on $x = a_1, \dots y = a_1, \dots$
- 1°. Let the singular integrals relative to $x = a_1, \dots$ be normal in \mathfrak{B} .
- 2°. Let the singular integrals relative to $y = \alpha_1, \dots$ be uniformly evanescent in any interval of $\mathfrak A$ not embracing the points a_1, \dots

Then

$$J(y) = \int_a^b f(x, y) dx$$

is integrable in B.

For, conditions 1°, 2°, 3° of 1 are obviously fulfilled. That 4° is satisfied, follows from 570.

- 627. 1. Let f(xy) be regular in $R = (ab\alpha\beta)$ except on the lines $x = a_1, \dots x = a_r; y = a_1, \dots y = a_s$.
- 1°. Let the singular integrals relative to the lines $x = a_1, \cdots$ be normal.
 - 2°. Let the integral

$$\int_{a}^{d} dx \int_{a}^{B} f dy$$

admit inversion, if (c, d) does not embrace the points a1, a2, ...

3°. Let

$$K = \int_{a}^{\beta} dy \int_{a}^{b} f dx$$

be convergent.

Then

$$L = \int_a^b dx \int_a^\beta f dy$$

is convergent, and K=L.

For simplicity, let x = b, $y = \beta$ be the only singular lines. Then, by 2°,

$$\int_{a}^{b} dx \int_{a}^{\beta} f dy = \int_{a}^{\beta} dy \int_{a}^{b} f dx, \quad b - \delta < b' < b.$$

$$= \int_{a}^{\beta} \int_{a}^{b} - \int_{a}^{\beta} \int_{b'}^{b}, \quad \text{since } K \text{ is convergent.}$$

$$= K - \int_{a}^{\beta} \int_{a}^{b}.$$
(2)

440

But, however small $\epsilon > 0$ is taken, we may take $\delta > 0$ so small that

$$\left| \int_{a}^{b} \int_{b}^{b} \left| < \epsilon, \text{ by } 620, 4 \right| \right|$$
 (8)

From 1), 2), 3) we have

$$\left| \int_a^y \int_a^a -K \right| < \epsilon, \qquad b-\delta < b' < b.$$

But then

$$L = \int_{a}^{b} \int_{a}^{\beta} = \lim_{\lambda \to 0} \int_{a}^{b} \int_{a}^{\beta} = K$$
2 Let $f(xy)$ be simply regular in $R = (aba\beta)$, except on $x = a_1$,

 $y=a_1$ 1° Let the singular integrals relative to the lines $x=a_1$ b

normal in \mathfrak{B} 2° Let the singular integrals relative to the lines $y = a_1$ be un

formly evanescent in any interval of A not embracing the points at

Then the integrals

$$\int_{-\infty}^{\infty} dy \int_{-\infty}^{\infty} f dx, \qquad \int_{-\infty}^{\infty} dz \int_{-\infty}^{\infty} f dy$$

are convergent and equal

For condition 2° of 1 is satisfied by 622, 2 if we replace x by y in that theorem — Condition 3° is fulfilled by 626, 2

628 Example As an application of 627 2 let us consider

$$\int_0^\beta dy \int_0^1 \frac{dx}{\sqrt{x}} = b \beta > 0$$

The singular lines are x = 0 y = 0

The angular integral relative to $x=\theta$

$$S = \int_0^{\infty} \frac{dx}{\sqrt{xy}}$$

is normal in $\mathfrak{B} = (0, \beta)$ For,

$$\mathcal{S} = \frac{1}{\sqrt{s}} \int_{1}^{s} \frac{dz}{\sqrt{z}} \simeq e^{t} F(y),$$

setting

$$\sigma = \int_{1}^{\infty} \frac{dz}{\sqrt{z}}, \ \sigma(y) = \frac{1}{\sqrt{y}}$$

Here, for any $\epsilon > 0$, there exists a $\delta > 0$ such that $\epsilon' < \epsilon$, for any $0 < a < \delta$. On the other hand, σ is integrable in \mathfrak{B} .

The singular integral

$$T = \int_0^a \frac{dy}{\sqrt{xy}}$$

relative to y = 0 is uniformly evanescent in any (a, b), a > 0. For,

$$T \leq \frac{1}{\sqrt{a}} \int_0^a \frac{dy}{\sqrt{y}} \cdot$$

But for any $\epsilon > 0$ there exists an $\alpha_0 > 0$, such that

$$\int_0^\alpha \frac{dy}{\sqrt{y}} < \epsilon \sqrt{a}, \qquad 0 < \alpha < \alpha_0.$$

Hence

$$T < \epsilon$$
 for any $\alpha < \alpha_0$

Thus the conditions of 627, 2 being fulfilled, both integrals

$$\int_0^\beta dy \int_0^\delta \frac{dx}{\sqrt{xy}}, \qquad \int_0^\delta dx \int_0^\beta \frac{dy}{\sqrt{xy}} \tag{1}$$

are convergent and equal.

This result is easily verified by actually evaluating these integrals. For,

$$\int_0^b \frac{dx}{\sqrt{xy}} = \frac{1}{\sqrt{y}} \int_0^b \frac{dx}{\sqrt{x}} = \frac{2\sqrt{b}}{\sqrt{y}}.$$

Hence

$$\int_0^\beta \int_0^b = 2\sqrt{b} \int_0^\beta \frac{dy}{\sqrt{y}} = 4\sqrt{b\beta}; \text{ etc.}$$

Differentiation

629. Let f(xy), $f'_{y}(xy)$ be regular in $R = (ab\alpha\beta)$, except on the lines $x = a_1, \dots x = a_r$.

1°. Let f'_{ν} be a semi-uniformly continuous function of y in $\mathfrak{B} = (\alpha \beta)$.

2°. In the elementary rectangles $(a_i - \tau, a_i + \tau, \alpha, \beta)$,

tet

$$|f_{\nu}'(xy)| \leq \phi_{\iota}(x), \qquad \iota = 1, 2, \dots r,$$

the ϕ 's being integrable in $(a_1 - \delta, a_1 + \delta)$.

Then

$$\frac{dJ}{dy} = \frac{d}{dy} \int_a^b f(xy) dx = \int_a^b f_y'(xy) dx, \quad \text{in } \mathfrak{B}.$$
 (1)

For simplicity, let x = b be the only singular line, and let f_x^* be uniformly continuous in $\mathfrak{A} = (a, b)$, except at b Then

$$\frac{\Delta J}{\Delta y} = \int_{s}^{s} \frac{f(x \ y + h) - f(x \ y)}{h} dx, \quad |h| < \delta$$

$$= \int_{s}^{s} f'_{s}(x \ \eta) dx, \quad \text{by Law of Neau}$$

$$= \int_{s}^{s} f'_{s}(xy) dx + \int_{s}^{s} |f'_{s}(xy) - f'_{s}(xy)| dx$$

$$= \int_{s}^{s} f'_{s}(xy) dx + D \qquad (2$$

But

442

But
$$D = \int_{0}^{b} \{f_{\psi}^{*}(xy) - f_{\psi}^{*}(xy)\} dx = \int_{0}^{b} + \int_{0}^{b} = D_{1} + D_{1}$$

Also, by 2^b, $|f_{\psi}^{*}(xy) - f_{\psi}^{*}(xy)| \le 2 \phi(x)$

Hence

$$|D_2| \le 2 \int_{s}^{s} \phi dx < \frac{\epsilon}{2}$$

provided b' is taken sufficiently near b

On the other hand, f'_{k} being uniformly continuous in $\mathfrak{A}' = (a, b')$ we can take & so small that

$$|f_{\theta}(x, \eta) - f_{\theta}(x, y)| < \frac{\epsilon}{2(b-a)}, \quad \text{in } \emptyset$$

Then

(27 1 log x dz n > 0 integral

 $f(xy) = x^{y-1} \log^n x$ is not defined for z = 0 Let us give it the value 0 when z = 0 Then

$$f_x(x, y) = x^{y-1} \log^{n+1} x \qquad \text{for } x > 0$$

Then f and f_x^* are simply regular in $R = (0, 1, \alpha, \beta)$, $\alpha > 0$ except on the line x = 0. Moreover, f_x^* is a uniformly continuous function of y in $\mathfrak{B} = (\alpha, \beta)$, except possibly on the line x = 0. It is therefore a regularly continuous function of y in \mathfrak{B} . Thus condition 1° of 629 is fulfilled. Condition 2° is also satisfied, as 614, 2) shows Hence if we set

$$J=\int_0^1 x^{y-1}\,dx,$$

we get, by 629,

$$\frac{dJ}{dy} = \int_0^1 x^{y-1} \log x \, dx;$$

or differentiating n times,

$$\frac{d^nJ}{dy^n} = \int_0^1 x^{y-1} \log^n x \, dx.$$

But, by 575, Ex. 3,

$$J = \frac{1}{y}$$

Hence

$$\frac{d^n J}{dy^n} = (-1)^n \frac{n!}{y^{n+1}}.$$

Comparing 1), 2), we get

$$\int_0^1 x^{y-1} \log^n x \, dx = (-1)^n \frac{n!}{y^{n+1}}, \qquad y > 0.$$
 (3)

631. 1. By using double integrals, we can obtain more general conditions than those given in 629, for differentiating under the integral sign in

 $J = \int_a^b f(xy) dx.$

For example, the following.

Let f(x, y), $f'_{\nu}(x, y)$ be in general regular with respect to x in $R = (aba\beta)$.

1°. Let $f'_{y}(xy)$ be a semi-uniformly continuous function of y in $\mathfrak{B} = (\alpha, \beta)$.

2°. Let

$$g(y) = \int_a^b f_{\nu}'(xy) dx$$

be uniformly convergent in B.

3°. Let

$$\int_{y}^{y+h} dy \int_{a}^{b} f_{y}'(x, y) dx, \qquad |h| < \delta$$

admit inversion.

Then

$$\frac{dJ}{dy} = \int_a^b f_v'(xy) dx, \quad \text{in } \mathfrak{B}.$$
 (1)

$$\frac{\Delta y}{\Delta y} = \frac{1}{h} \left\{ \int_{0}^{\infty} [f(x, y + h) - f(x, y)] dx \right\}$$

$$= \frac{1}{h} \int_{0}^{\infty} dx \int_{0}^{\infty} f'(x, y) dy \qquad \text{by 605, 610, 6}$$

$$= \frac{1}{h} \int_{0}^{\infty} dx \int_{0}^{\infty} f'(x, y) dy \qquad \text{by 3}^{\infty}$$

$$= \frac{1}{h} \int_{0}^{\infty} f'(y) dy$$

(2 But by 1°, 2°, and 61% 1 g(y) is continuous in B Thus on

passing to the limit &= 0 in ...) we get 1) using 537, 2

2 As a corollary of 1 we have Let

Let f(zy) $f_*(zy)$ be regular in $R = ata\beta$, except on the lines $z = a_1 \quad z = a_n$ Let f.(zw) be continuous in R except on these lines

 $\int_{-\infty}^{\infty} (x \ y) dx$

be uniformly convergent in $\mathfrak{B} = \alpha \beta$

$$\frac{d}{dx} \int_{0}^{x} f(xy) dx \approx \int_{0}^{x} f(xy) dx$$

$$\frac{d}{dx} \int_{0}^{x} f(xy)dx \approx \int_{0}^{x}$$

 $\frac{d}{dx} \int_{0}^{x} f(xy)dx = \int_{0}^{x} f'_{y}(xy)dx,$

CHAPTER XV

IMPROPER INTEGRALS. INTERVAL OF INTEGRATION INFINITE

Definitions

632. 1. If f(x) has no points of infinite discontinuity in $\mathfrak{A} = (a, \infty)$, and is integrable in any partial interval (a, b), of \mathfrak{A} , we shall say that f(x) is regular in \mathfrak{A} . If on the contrary, f(x) has a finite number of points of infinite discontinuity c_1, c_2, \cdots in \mathfrak{A} , but is integrable in any partial interval (a, b), we shall say f(x) is in general regular in \mathfrak{A} . The points c_1, c_2, \cdots are singular points.

Let f(x) be in general regular in \mathfrak{A} . Let us eonsider

$$\lim_{x=\infty}\int_{a}^{x}f(x)dx,$$
 (1)

which we denote more shortly by

$$\int_{a}^{x} f(x)dx,$$
 (2)

and which is called the integral of f(x) from a to $+\infty$, or the integral of f(x) in \mathfrak{A} .

If the limit 1) is finite, we say the integral 2) is convergent or that f(x) is integrable in \mathfrak{A} . If the limit 1) is infinite, the integral 2) is divergent. If the limit 1) does not exist, i.e. if it is neither finite nor definitely infinite, the integral 2) does not exist.

If |f(x)| is integrable in \mathfrak{A} , f(x) is absolutely integrable in \mathfrak{A} , and the integral 2) is absolutely convergent.

2. We make a remark here which will often enable us to simplify our demonstrations, without loss of generality.

If f(x) is in general regular in $A = (a, \infty)$, we can take b so large that f(x) is regular in (b, ∞) But the integral

$$\int f(x)dx$$

has been treated in Chapter $\ensuremath{\text{VIV}}$. We have thus only to consider

$$\int f(x)dx$$

in which the integrand is regular We may therefore often as sume in our demonstration, without loss of generality, that f(x) is regular in $\mathfrak A$

For
$$\int_{1}^{\infty} \frac{dx}{x^2} - 1$$
 it is convergent.

For, $\lim_{x \to \infty} \int_{1}^{\infty} \frac{dx}{x^2} = \lim_{x \to \infty} \left(1 - \frac{1}{x}\right) = 1$

For, $\lim_{x \to \infty} \int_{1}^{\infty} \frac{dx}{x^2} = +\infty$ it is divergent.

For, $\lim_{x \to \infty} \int_{1}^{\infty} \cos x \, dx = \dim \sin x$ in $\lim_{x \to \infty} \int_{1}^{\infty} \cos x \, dx = \dim \sin x$

633 1 General criterion for convergence Let f(x) be regular in $\mathfrak{A} = (a, \infty)$ For

to be convergent it is necessary and sufficient that, for each $\epsilon > 0$, there exists a G > 0, such that

$$\int f dx | < \epsilon$$

for any pair of numbers a, B € G

This is a direct consequence of 284

2. The integral 2) is perfectly analogous to the singular integrals considered in Chapter XIV. It is convenient to eall it the singular integral relative to the point $x = \infty$; and also to call this point a singular point.

Instead of 2) it is convenient at times to call

$$\int_{b}^{x} f(x)dx, \qquad b > G,$$
 (3)

the singular integral. The integrals 2) and 3) are obviously equivalent.

3. Let f(x) be regular in $\mathfrak{A} = (\alpha, \infty)$. If f(x) is absolutely integrable in \mathfrak{A} , it is also integrable in \mathfrak{A} .

For by hypothesis

$$\int_{\alpha}^{\beta} |f(x)| dx < \epsilon, \qquad G < \alpha < \beta.$$

But in any given (α, β) , f(x) is integrable by hypothesis and

$$\left|\int_a^\beta f dx\right| \le \int_a^\beta |f| dx$$
, by 528, 1.

4. The reader should note that an integral may be convergent and yet not absolutely convergent. Thus

$$\int_0^\infty \frac{\sin x}{x^\mu} dx$$

converges for $0 < \mu \le 1$, while

$$\int_0^\infty \frac{|\sin x|}{x^\mu} dx$$

is divergent for these values of μ . Cf. 646, Ex. 2.

634. 1. The symbol

$$\int_{-\infty}^{a} f(x) dx \tag{1}$$

is defined as

$$\lim_{\alpha \to -\infty} \int_a^a f(x) dx,$$

and is called the integral of f(x) from $-\infty$ to a.

The symbol

$$\int_{-}^{} f(x)dx$$

(2

15 defined as

$$\lim_{x \to \infty} \int_a^b f(x) dx$$

The terms introduced in 63° have a similar meaning here. The integral 1) is not essentially different from

$$\int_{a}^{a} f(x) dx$$

and requires therefore no comment

2 In regard to 2) we have the theorem

Let f(x) be an general regular an $(-\infty \infty)$. In order that

$$J = \int_{-\infty}^{\infty} f dx$$

be convergent at as necessary and sufficient that

$$J_1=\int_a^a f dx \quad J_2=\int_a^a f dx$$

be convergent for any a When I is convergent

$$J = J_{-} + J_{-}$$

If J is convergent we have

$$\epsilon > 0$$
 $G > 0$ $\left| J - \int_{\epsilon}^{\beta} \left| < \frac{\epsilon}{2} \right| < G$ $\beta > G$

$$\left|J-\int_a^a\right|<rac{\epsilon}{2}$$
 $\alpha<-G$

Subtracting we get

$$\left|\int_{a}^{a}-\int_{a}^{a}\right|<\epsilon$$

$$\left|\int_{a}^{a}fdx\right|<\epsilon$$

or

Hence, by 633,

$$\int_{-\infty}^{a} f dx$$

$$\int_{-\infty}^{\infty} f dx$$

Similarly, is convergent.

$$\int_a^{\infty} f dx$$

Therefore when J is convergent, J_1 , J_2 are conis convergent. vergent.

Conversely, if J_1 , J_2 are convergent, J is convergent.

For, let a be fixed and $\alpha < a < \beta$.

$$\int_a^\beta = \int_a^a + \int_a^\beta, \quad \text{by 593.}$$

For a sufficiently large G, and $\epsilon > 0$ arbitrarily small,

$$\begin{split} \int_a^a &= J_1 + \epsilon', \qquad \alpha < -G, \ |\epsilon'| < \frac{\epsilon}{2} \\ \int_a^\beta &= J_2 + \epsilon'', \qquad \beta > G, \ |\epsilon''| < \frac{\epsilon}{2} \\ \left| \int_a^\beta - (J_1 + J_2) \right| < \epsilon, \end{split}$$

Hence

for all $\alpha < -G$, and $\beta > G$. Therefore

$$\lim \int_a^\beta = J_1 + J_2.$$

Hence, when J_1 , J_2 are convergent, J is, and

$$J = J_1 + J_2.$$

3. As a result of the foregoing, we see that the integrals

$$\int_{-\infty}^{a} f dx, \int_{-\infty}^{\infty} f dx \tag{3}$$

do not differ essentially from

$$\int_{a}^{\infty} f dx.$$

For convenience, we shall therefore study only this last; the results we obtain are then readily extended to the integrals 3).

Tests for Conservence

635 1 The μ tests for convergence Let f(x) be regular in $\mathbb{E} = (a \infty)$ If there exists a $\mu > 1$, such that

$$x^{\mu}|f(x)| < M, M > 0, \quad in V(\infty),$$

f(x) is absolutely integrable in \mathfrak{A} For let $G < \alpha < \beta$ be in V. Then, by 526, 2

$$\left|\int_{a}^{a} f dx\right| \leq \int_{a}^{b} |f| dx \leq \int_{a}^{a} \frac{M}{m} dx = \frac{M}{n-1} \left\{ \frac{1}{n^{n-1}} - \frac{1}{2n-1} \right\},$$

< . if G is taken sufficiently large

2 Let f(x) be regular in U=(a x) If for some \mu>1

$$m x^{\mu}(f(x))$$

us finite, f(x) is absolutely integrable in A

3 As corollary of 2 we have

In
$$\mathfrak{A} = (a, \infty), a > 0$$
 let

 $f(z) = \frac{g(z)}{z}$ or $\frac{x \cdot g(z)}{e^{z}}$, $\lambda > 1 > 0$, where g is limited in $\mathfrak A$ and integrable in $\mathfrak A$ absolutely integrable in $\mathfrak A$

636 Test for divergence Let f(x) be regular in $\mathbb{N} = (a, \infty)$ In $V(\infty)$ let f have one supp g and

Then

$$\sigma x f(x) > M$$
 $M > 0$

 $J = \int_{a}^{x} f dx = \sigma \quad x.$ For, let a < a < x, while $a \times b = m \cdot V$

Then

Now, by 526, 2,

$$\int_a^x = \int_a^x + \int_a^x$$

 $\int_{a}^{x} \sigma f dx \ge M \int_{a}^{x} \frac{dx}{x} = M \log \frac{x}{a} = +\infty,$

when $x = +\infty$

637. Logarithmic test for convergence. Let f(x) be regular in $\mathfrak{A} = (a, \infty)$. If there exists a $\mu > 1$, and an s, such that

$$xl_1xl_2x \cdots l_{s-1}xl_s\mu x|f(x)| < M, \quad in V(\infty),$$

f(x) is absolutely integrable in \mathfrak{A} .

We leave, by 389, 2), for x > 0 sufficiently large,

$$D_{x}l_{s}^{1-\mu}x = \frac{1-\mu}{xl_{1}xl_{2}x\cdots l_{s-1}xl_{s}^{\mu}x}.$$

Hence, if $0 < G < \alpha < \beta$,

$$\int_{a}^{\beta} \frac{dx}{x l_{1} x \cdots l_{s}^{\mu} x} = \frac{1}{\mu - 1} \left\{ \frac{1}{l_{s}^{\mu - 1} a} - \frac{1}{l_{s}^{\mu - 1} \beta} \right\} \doteq 0,$$

when $G \doteq +\infty$.

Now

$$\left| \int_a^\beta \! f dx \right| \leq \int_a^\beta \left| f \right| dx \leq M \! \int_a^\beta \! \frac{dx}{x l_1 x \cdots l_s^\mu x}$$

 $<\epsilon$, for G sufficiently large.

638. The logarithmic test for divergence. Let f(x) be regular in $\mathfrak{A} = (a, \infty)$. In $V(\infty)$, let f(x) have one sign σ , and

$$xl_1xi_{2^{\lambda}} \qquad l : \sigma \cdot \sigma f(x) > M > 0.$$

Then

$$\int_a^\infty f dx = \sigma \cdot \infty.$$

For,

$$\int_a^x = \int_a^a + \int_a^x.$$

But

$$\int_a^x \! \sigma f dx > M \int_a^x \! \frac{dx}{x l_1 x \cdots l_s x} = M l_{s+1} \frac{x}{a},$$

since by 389, 1), for sufficiently large x > 0,

$$D_x l_{s+1} x = \frac{1}{x l_1 x \cdots l_s x}, \qquad l_0 \approx 1.$$

As

$$\lim_{n\to\infty}l_{s+1}\frac{x}{a}=+\infty,$$

our theorem is established.

452 639 Ex. 1. A quarter period of Jacobs a function an (u, s) is

$$K = \int_{1/a}^{a} \frac{dx}{\sqrt{(1-x^2)(1-x^2x^2)}}, \quad 0 < x < 1.$$

The point $x = 1/\epsilon$ is the only finite singular point. Applying the μ test of 579 at this point, we see that we can take a = 4 The engular integral at this point is therefore evanescent. Consider now the point x = 0 We have

$$\frac{1}{\sqrt{(1-x^2)(1-x^2x^2)}} = \frac{1}{x^2\sqrt{\left(1-\frac{1}{x^2}\right)\left(x^2-\frac{1}{x^2}\right)}}$$

This shows that the a test of 635 is satisfied for any a 22 Hence the singular integral relative to this point is evanescent. Hence K is convergent.

640 Ex 2 A half period of Weierstraus a function p(n q1, q1) is

$$u = \int_{0}^{\infty} \frac{dx}{\sqrt{x^2 + x^2}}$$

where e is the largest real root of

The point of is the only finite sungular point. Applying the a test of 579 at this point, we see that we can take #= } lience the singular integral relative to this point is evanescent. Consider the point x = @ We have

$$\frac{1}{\sqrt{4 \, x^2 - g_0 x - g_0}} = \frac{1}{x^{\frac{3}{2} \sqrt{4 - \frac{g_0}{g_0^2} - \frac{g_0}{g_0^2}}}}$$

This shows that the a test of 633 is establed for any a \$1. Hence was convergent.

641 Ex 3 The Heta function.

$$B(u, v) = \int_{0}^{\infty} \frac{x^{u-1}dx}{(1+x)^{u+v}}$$
(1)

The point z = 0 is a singular point if u < 1 Applying the tests of 579, 580 at this point, we see that

$$\int_0^a \frac{x^{a-1}dx}{(1+x)^{a+a}}, \quad a>0,$$

is convergent when a >0, and divergent, when a >0 Consider the point z = 10 We have

$$f(z) = \frac{z^{\alpha-1}}{(1+z)^{\alpha+\alpha}} = \frac{1}{z^{\alpha+1}} \frac{1}{\left(1+\frac{1}{z}\right)^{\alpha+\alpha}}$$

Applying now the tests of 635, 636, we see that

$$\int_{u}^{\infty} f(x) dx, \qquad u > 0.$$

converges for v>0, and diverges for $v \ge 0$.

Thus the integral 1) has a finite value for every u, v > 0. The function so defined is called the Eulerian integral of the first kind or the Beta function.

642. Ex. 4. The Gamma function,

$$\Gamma(u) = \int_0^\infty e^{-x} x^{u-1} dx. \tag{1}$$

The point x=0 is a singular point if u<1.

Applying the tests 579, 580 at this point, we see that

$$\int_0^a a > 0.$$

is convergent when u > 0, and divergent when $u \ge 0$.

On the other hand, applying the μ test of 635, 3, we see that

is convergent for any u. The integral 1) therefore defines a function of u for all u > 0. It is called the Eulerian Integral of the second kind or the Gamma function.

643. 1. Let f(x) be regular and integrable in any partial interval (a, b), of $\mathfrak{A} = (a, \infty)$.

$$\int_{a}^{x} f(x) dx$$

be limited in A.

In $V(\infty)$, let g(x) be monotone, and $g(\infty) = 0$.

Then f(x)g(x) is integrable in \mathfrak{A} .

We apply the criterion of 633. Let $G < \alpha < \beta$ lie in $V(\infty)$. Then by the Second Theorem of the Mean, 545,

$$\int_{\alpha}^{\beta} f g dx = g(\alpha + 0) \int_{\alpha}^{\xi} f dx + g(\beta - 0) \int_{\xi}^{\beta} f dx, \qquad \alpha \le \xi \le \beta.$$

We can take G so large that

$$g(\alpha+0), \quad g(\beta-0)$$

are numerically as small as we please. As the integrals on the right are numerically less than some fixed number, we have

$$\left|\int_{\varepsilon}^{\beta} f g dx\right| < \epsilon$$

for any pair of numbers α , $\beta > G$. Hence fg is integrable in \mathfrak{N} .

 Let f(x) be regular and integrable in A = (a ∞) Let g(x) be limited and monotone in A

Then for is integrable 12 M

For by 545

$$\int_{a}^{a} f g dx = g(a+0) \int_{a}^{a} f dx + g(p-0) \int_{a}^{a} f dx \tag{1}$$

Let

 $|\phi(x)| < M$ Since f is integrable in I we can take you large that

$$\left|\int_{t}^{t} f dx\right| = \left|\int_{t}^{t} f dx\right| < \frac{\epsilon}{9 \, \text{M}} \qquad \alpha, \beta > \gamma$$

Then the right side of 1) is numerically < e Hence fg is integrable

3 Let f(x) be regular and absolutely integrable in A-(a x) Let g(x) be la nited and integrable in A Then f(x)g(x) is absolutely integrable in A

We have only to show by 633 that

$$\epsilon > 0$$
 $\theta > 0$ $\int_{a}^{b} fg|dx < \epsilon$ (1)

for any pair of numbers # B> G No v o(x) being limited we have

Hence

This in 2) gives 1)

$$g(x) < M$$
 in \mathfrak{A}

$$\int_{0}^{a} fg \, dx \le M \int_{0}^{A} f \, dx \tag{2}$$

But f(x) being absolutely integrable in X we can take G so large that

$$\int_{a}^{b} |f| dx < \frac{\epsilon}{M} \qquad \alpha \beta > G$$

644 Let f(x) be in general regular in X=(a in) but not inte rable in M Let

$$\int_{x}^{x} f(x)dx$$
(1)

be limited in \mathfrak{A} . Let g(x) be monotone in \mathfrak{A} and $g(\infty) = G \neq 0$. Then

 $\int_{a}^{a} f(x)g(x)dx \tag{2}$

is not convergent.

For, if 2) were convergent, we would have

$$\epsilon > 0,$$
 $b,$ $\left| \int_a^\beta f g dx \right| < \epsilon,$ $\alpha, \beta > b.$

But this is impossible. For

$$\int_{\alpha}^{\beta} f y dx = g(\alpha + 0) \int_{\alpha}^{\xi} f dx + g(\beta - 0) \int_{\xi}^{\beta} f dx.$$
 (3)

Let the integral 1) be numerically < M.

We can take b so great that

$$|g(x)-G|<\sigma, x>b,$$

where σ is small at pleasure.

We can therefore write 3)

$$\int_{a}^{\beta} f g dx = (G + \sigma') \int_{a}^{\xi} f dx + (G + \sigma'') \int_{\xi}^{\beta} f dx, \qquad |\sigma'|, \ |\sigma''| < \sigma.$$

Henee

$$\left| \int_a^{\beta} f dx \right| \le \frac{\epsilon + 4 \sigma M}{|G|} < \epsilon', \quad \epsilon' \text{ small at pleasure,}$$

which states that f(x) is integrable in \mathfrak{A} .

645. Ex. 1. For what values of μ does

$$J = \int_0^\infty \frac{\cos x}{x^\mu} dx$$

converge? Set

$$J_1 = \int_0^a \frac{\cos x}{x^{\mu}} dx, \qquad J_2 = \int_a^{\infty} \frac{\cos x}{x^{\mu}} dx; \qquad a > 0.$$

The integral J_2 is convergent by 643, 1, provided $\mu > 0$. For $\mu \ge 0$, it obviously does not converge. The integral J_1 is convergent, as we saw, 586, only when $\mu < 1$. Thus J is convergent when and only when

646 Ex. 2 $J = \int_0^{\sin x} dx.$

 $J = \int_0^{\infty} \frac{\sin x}{x^2} dx.$

Set $J_1 = \int_0^a \frac{\sin x}{x^a} dx, \quad J_2 = \int_a^a \frac{\sin x}{x^a} dx, \quad a > 0$ In 687 we saw J_1 is convergent only when a < 2

In 687 we saw J₁ is convergent only when $\mu > 0$ When $\mu \ge 0$ at obviously does not converge.

Hence J is convergent when and only when,

 $0 < \mu < 2$ That J does not converge absolutely for $0 < \mu \le 1$ is shown as follows. We have

$$K_a = \int_0^{e_T} \frac{\sin x \, dx}{x^a} = \int_0^e + \int_e^{e_T} + \dots + \int_{(a-b)e}^{e_T}$$

$$= J_1 + J_2 + \dots + J_{e_T}$$
Let

et 2 - g + (m - l)s

Then $J_m = \int_0^{\pi} \frac{\sin y \, dy}{iy + (m-1)\pi_i^m} > \frac{1}{(m\pi)^n} \int_0^{\pi} \sin y \, dy = \frac{2}{(m\pi)^m}$

Hence $K_1 > \frac{2}{1} + \frac{1}{1} + \frac{1}{1} + \frac{1}{1} = x$

when a m m as the reader probably knows or as will be shown later.

Properties of Integrals

647 In Chapter XIV we established the properties of the improper integrals,

by a passage to the limit. We propose now to develop the properties of improper integrals, the interval of integration being infinite, by a similar method. In many cross the reasoning is so similar to that employed to prove the corresponding theorems in Chapter AIV, that we shall not repet it, referring the reader to the demonstrations given in that chapter.

648 1. Let f(x) be integrable in (a w) Then

$$\int f dx = - \int f dx$$

2. Let f(x) be integrable in (a, ∞) . Then

$$\int_{a}^{\infty} f dx = \int_{a}^{b} f dx + \int_{b}^{\infty} f dx, \qquad a < b.$$

3. Let $f_1(x) \cdots f_m(x)$ be integrable in (a, ∞) . Then

$$\int_a^{\infty} (c_1 f_1 + \cdots + c_m f_m) dx = c_1 \int_a^{\infty} f_1 dx + \cdots + c_m \int_a^{\infty} f_m dx$$

649. 1. Let f(x), g(x) be integrable in (a, ∞) . Except possibly at the singular points let $f(x) \leq g(x)$. Then

$$\int_a^\infty f dx \ge \int_a^\infty g dx.$$

2. Let f(x), g(x) be integrable in (a, ∞) . Except possibly at the singular points, let $f(x) \ni g(x)$. At a point c of continuity of these functions, let f(c) > g(c). Then

$$\int_{a}^{\infty} f dx > \int_{a}^{\infty} g dx.$$

- 3. Let $f(x) \equiv 0$ be integrable in (a, ∞) . At a point c of continuity of f, let f(c) > 0. Then $\int_{a}^{\infty} f(x) dx > 0.$
 - 4. Let f(x) be absolutely integrable in (a, ∞) . Then

$$\left| \int_a^{\infty} f dx \right| \leq \int_a^{\infty} |f| \, dx.$$

5. Let

$$J = \int_{a}^{\infty} f dx$$

be convergent. We may change the value of f(x) over a limited discrete aggregate, without altering the value of J, provided the new values of f are limited.

650. Let f(x) be integrable in $\mathfrak{A} = (a, \infty)$. Then

$$J(x) = \int_{-\infty}^{\infty} f dx \qquad a \le x.$$

is a continuous limited function of x in \mathfrak{A} .

For, by 648, 2,
$$\int_{a}^{\infty} = \int_{a}^{c} + \int_{a}^{\infty}, \quad c > z.$$

 $\int_{x}^{c} f dz$

is a continuous function of x in (a, e), by 603 As

$$\int_{a}^{\infty} f dx$$

18 a constant, J(x) is continuous in A

J is limited in a In fact, for each $\epsilon > 0$, there exists a ϵ such that

$$\left|\int_{\epsilon}^{\infty} f dx\right| < \epsilon$$

$$\int_{\epsilon}^{\epsilon} f dx,$$

But

458

But

being continuous in the limited interval (a, ϕ) , is limited. Hence J is limited in $\mathfrak A$

651 Let f(z) be integrable in $\mathfrak{A} = (a, \infty)$ Then

$$\frac{d}{dx}\int_{x}^{x}fdx=-f(x)$$

for any point x of % at which f(x) is continuous

$$J(x) = \int_x^x = \int_x^e + \int_e^x = K(x) + C_e$$

C being a constant By 604, 1,

$$\frac{dK}{dz} = -f(z)$$

Hence

$$\frac{dJ}{dx} = \frac{d(K+C)}{dx} = \frac{dK}{dx} = -f(x)$$

652 In $\mathfrak{A} = (a, \infty)$ let f(x) be continuous excepting possibly at certain points c_1 - c_i where it may be unlimited. Let it be integrable in any $(a \ b)$

Let F(x) be one-valued and continuous in \mathfrak{A} ; having f(x) as derivative except at the points c.

Then

$$\int_{a}^{x} f dx = F(+\infty) - F(a), \tag{1}$$

where $F(+\infty)$ is finite or infinite.

For, by 605,

$$\int_a^b f dx = F(b) - F(a),$$

however large b is. Passing to the limit, we get 1).

Theorems of the Mean

653. First Theorem of the Mean. In $\mathfrak{A} = (a, \infty)$ let g(x) be integrable and limited.

Let f(x) be integrable, and non-negative in \mathfrak{A} . Then

$$\int_{a}^{x} f g dx = \mathfrak{M} \int_{a}^{\infty} f dx, \tag{1}$$

where M is a mean value of g in A.

For, by 602,

$$m \int_{a}^{b} f dx \le \int_{a}^{b} f g dx = M \int_{a}^{b} f dx, \qquad a < b.$$
 (2)

where

$$m \le g(x) \le M$$
.

Let $b \doteq +\infty$; since all the integrals in 2) are convergent, by 643. 3. we get in the limit,

$$m \int_{a}^{\infty} f dx \le \int_{a}^{\infty} f g dx \le M \int_{a}^{\infty} f dx,$$

which gives 1).

654. Second Theorem of the Mean. In $\mathfrak{A}=(a,\infty)$, let f(x) be integrable and g(x) limited and monotone. Then

$$J = \int_{a}^{x} f(x)g(x)dx \approx g(a+0)\int_{a}^{\eta} f(x)dx + g(\infty)\int_{\eta}^{\infty} f(x)dx, \quad (1$$

If $g(a+0)=g(+\infty)$ the theorem is obviously true We may therefore assume that these himis are different Next we observe that the integral J is convergent, by 599, 2 and 643, 2

To fix the ideas, let g(x) be monotone increasing Let b be arbitrarily large. Then, by 608,

$$\int_{a}^{b} f g dx = g(a+0) \int_{a}^{b} f dx + g(b-0) \int_{a}^{b} f dx$$
 (2)

Let us add

$$B = g(+\infty) \int_{1}^{\infty} f dx$$

to both sides of 2), observing that

460

$$\lim_{n \to \infty} B = 0 \tag{6}$$

We get
$$\int_a^b fg dx + B = g(a+0) \int_a^b f dx + g(b-0) \int_a^b f dx + g(+\infty) \int_a^\infty f dx$$

$$= g(a+0) \int_a^\infty f dx - g(a+0) \int_a^\infty f dx + g(b-0) \int_a^\infty f dx$$

$$-g(b-0) \int_a^\infty f dx + g(+\infty) \int_a^\infty f dx$$

$$= g(a+0) \int_a^\infty f dx + \left\{ g(b-0) - g(a+0) \right\} \int_a^\infty f dx$$

$$+ \left\{ g(+\infty) - g(b-0) \right\} \int_a^\infty f dx$$

$$= g(a+0) \int_a^\infty f dx + U + V + V$$
(4)

Let λ, μ be the minimum and maximum of

 $\int_{-\infty}^{\infty} f dx$ Then obviously, în M

 $\lambda \leq \int_{a}^{\infty} f dx \leq \mu_{1}$

$$\lambda \leq \int_{0}^{\infty} f dx \leq \mu$$

Hence

$$\{g(b-0) - g(a+0)\} \lambda \le U \le \{g(b-0) - g(a+0)\} \mu,$$

$$\{g(+\infty) - g(b-0)\} \lambda \le V \le \{g(+\infty) - g(b-0)\} \mu.$$

Adding, we get

$$\{g(+\infty)-g(a+0)\}\lambda \leq U+V \leq \{g(+\infty)-g(a+0)\}\mu.$$

Hence

$$U + V = \mathfrak{M}' \{ g(+\infty) - g(a+0) \},$$

$$\lambda < \mathfrak{M}' < \mu.$$
(5)

" here

$$\int_{a}^{b} f g dx + B = g(a+0) \int_{a}^{\infty} f dx + \mathfrak{M}' \{ g(+\infty) - g(a+0) \}.$$

Passing to the limit $b = \infty$, and using 3), we have

$$J = g(a+0) \int_{a}^{\infty} f dx + \mathfrak{M} \left\{ g(+\infty) - g(a+0) \right\}; \tag{6}$$

where

$$\lim \mathfrak{M}' = \mathfrak{M},$$

and

$$\lambda \leq \mathfrak{M} \leq \mu$$
.

The integral

$$\int_{x}^{\infty} f dx$$

being a continuous function of x in (a, ∞) , must take on the value \mathfrak{M} for some point $x = \eta$, finite or infinite, in this interval. Then

$$\mathfrak{M} = \int_{\eta}^{\infty} f dx.$$

From 6) we have now,

$$J = g(a+0) \int_{a}^{\infty} f dx + \left\{ g(+\infty) - g(a+0) \right\} \int_{\eta}^{\infty} f dx$$
$$= g(a+0) \int_{a}^{\eta} f dx + g(+\infty) \int_{\eta}^{\infty} f dx,$$

which is 1).

Change of Variable

655 Let B = (a, β) a ≤ β, either a or β may be infinite Let z = ψ(u) have a continuous derivative in B which may vanish over a discrete aggregate, but has otherwise one sign

Let A = (a, b) be the image of B, where

$$a = \lim \psi(u), b = \lim \psi(u),$$

and b may be infinite

Let f(x) be integrable in any (a, b'), b' < b

If now, either

$$J_s = \int_0^s f(x)dx$$
, or $J_s = \int_0^s f[\psi(u)]\psi'(u)du$

us convergent, the other us, and both are equal

There are various cases Let us take the following as illustration Let $\mathfrak{A}=(a\ \infty)$ $\mathfrak{B}=(a,\infty)$ By virtue of 403, the points of \mathfrak{A} and \mathfrak{B} are in 1 to 1 correspondence

Let b' β be corresponding points in \mathfrak{A} . \mathfrak{B} Then as $\beta' = \infty$, $b' = \infty$ also, and conversely

By 606, 2,
$$\int_{0}^{x} f(x)dx = \int_{0}^{x} f[\psi(u)]\psi'(u)du$$
 (1

Suppose J_x is convergent. Then 1) shows, passing to the limit, that J_x is convergent and $J_x = J_x$. The supposition that J_x is convergent leads to a similar conclusion for J_x .

656 Ex. 1 Consider the convergence of

$$J = \int_0^z \sin x^2 dx$$

Since the integrand is continuous, J converges if

$$J_x - \int_1^\infty \sin x^2 dx$$

converges. Let $\mathbf{z} = \psi(\mathbf{z}) = \sqrt{\mathbf{z}}$

Then

which is convergent by 646 fience, by 655, J., and therefore J. is convergent. Ex. 2. We found, by 630, 3), that

$$\int_0^1 x^{y-1} \log^n x \, dx = \frac{(-1)^n n!}{y^{n+1}}, \quad y > 0.$$
 (1)

Let us set

$$x = \psi(u) = e^{-u}.$$

Here

$$a=0, b=1; \alpha=+\infty, \beta=0.$$

In B,

$$\psi'(u) = -e^{-u}$$

is continuous and always negative.

$$J_{u} = -(-1)^{n} \int_{+\infty}^{0} e^{-uy} u^{n} du$$
 (2)

is convergent, since 1) is. Hence 1), 2) give

$$\int_0^\infty e^{-uy} u^n \, du = \frac{n!}{y^{n+1}}, \qquad y > 0.$$
 (3)

657. 1. Stoke's Integrals. Let us consider the convergence of the integral

$$J = \int_0^\infty x \sin(x^3 - xy) dx,\tag{1}$$

which comes up in the theory of the Rainbow.

Let us set

$$u = x^3 - xy = x(x^2 - y) = \phi(x).$$
 (2)

The graph of this is a curve which crosses the axes at the points x=0, $x=\pm\sqrt{y}$, if y>0; and at the point x=0, if y=0. To fix the ideas, let us suppose y>0; the case when $y \ge 0$ may be treated in a similar manner.

Supposing, therefore, y>0, the graph of 2) shows that as x ranges over $\mathfrak{A}=(\sqrt{y},\infty)$, u ranges over $\mathfrak{B}=(0,\infty)$, the correspondence between the points of \mathfrak{A} and \mathfrak{B} being uniform. Thus the relation defines a one-valued inverse function $x=\psi(u)$ in \mathfrak{B} .

Let us write 1)

$$J = \int_0^{\sqrt{y}} + \int_{\sqrt{y}}^{\infty},$$

and denote the latter integral by J_x .

The corresponding integral in u is

$$J_u = \int_0^\infty g(u) \sin u \, du,$$

sctting

$$g(u) = \frac{x}{3x^2 - y}$$

We can now apply 643, 1. For, $x \doteq +\infty$ as $u \doteq +\infty$. Hence g(u) is a monotone decreasing function, for any positive y, and $g(\infty) = 0$. Thus J_u is convergent. Hence J_x is; and therefore the integral J is convergent.

2. The same considerations show à fortiori, that

$$K = \int_0^\infty \cos(x^3 - xy) dx \tag{8}$$

is convergent for any y.

3 In connection with these integrals occurs another integral

$$L = \int_0^n x^2 \cos(x^2 - xy) dx \qquad (6)$$

which it is important to show is not convergent. In fact effecting the change of variable defined by 2) in

$$L_1 - \int_0^{\infty} z^2 \cos(x^2 - zy) dz$$

supposing to fix the ideas that y > 0 we get

$$L_u - \int_0^u \frac{x^3}{3x^3 - y} \cos u \, du = \int_0^u h(u) \cos u \, du$$

Here h(u) is a monotone funct on and

h(∞) ≈ }

Thus L. is divergent, by 644 Hence L. is. Therefore L is divergent.

INTEGRALS DEPENDING ON A PARAMETER

Uniform Convergence

- 658 1 Let f(x, y) be defined at each point of the rectangle $B = (a \times a\beta)$ β finite or infinite Let $X = (a \times a)$ $B = (a, \beta)$
 - We shall say f(xy) is regular in R when 1° f(xy) has no point of infinite discontinuity in R
 - 2º f(xy) is integrable in M for each y in &
- At times we shall need to integrate f(xy) with respect to y In this case we shall also suppose
 - 3° f(xy) is integrable in 9 for each x in 2
- 2 If f(xy) is regular in R except that it may have points of infinite discontinuity on certain lines $x=a_1$ $x=a_n$ we shall say f(xy) is regular in R except on the lines $x=a_1$ or that it is in general regular with respect to x
- 3 Let us suppose that the points of infinite discontinuity of f(xy) do not be all on a finite number of lines parallel to the y axis but that is in excessive to employ in addition a finite number of lines parallel to the x-axis. To fix the ideas let these lines be $x=a_1-x=a_1-y=a_1-y=a_1$. If f(xy) is otherwise regular in B, x is if it employs properties 2, 2, 3 of 558, we shall say

f(xy) is in general regular with respect to x, y, or f(xy) is regular except on the lines $x = a_1, \dots y = a_1, \dots$

- 4. Let f(xy) be continuous at each point of R except on certain lines $x = a_1, \dots x = a_r$; $y = a_1, \dots y = a_s$. On the lines $x = a_1, \dots$ it may have points of infinite discontinuity; on the lines $y = a_1, \dots$ it may have finite discontinuities. If f(xy) is otherwise regular in R, we shall say it is simply regular with respect to x except on the lines $x = a_1, \dots$ or that it is simply irregular with respect to x.
- 5. Let f(xy) be continuous at each point of R except on the lines $x = a_1, \dots x = a_r$; $y = a_1, \dots y = a_s$. As in 3, let us suppose that all the points of infinite discontinuity cannot be brought on the lines $x = a_1, \dots$ Let f(xy) be otherwise regular. We shall say f(xy) is simply irregular with respect to x, y, or that it is simply regular except on the lines $x = a_1, \dots y = a_1, \dots$
- 6. The lines $x = a_1$, ... $y = a_1$, ... or which are grouped the points of infinite discontinuities of f(xy), are called singular lines. To each of these belong right and left hand singular integrals as in Chapter XIV. Cf. 666.
 - 7. The integral $\int_x^{\infty} f(xy) dx, \quad x \not \ni G,$ (1)

where G is large at pleasure, is called the singular integral relative to the line $x = \infty$.

If for each $\epsilon > 0$ there exists a G, such that 1) is numerically $< \epsilon$ for any y in \mathfrak{B} and every $x \not\equiv G$, we say 1) is uniformly evanescent in \mathfrak{B} .

8. If the singular integrals relative to the lines $x = a_1$, $x = a_n$ as well as the singular integral relative to the line $x = \infty$ are uniformly evanescent in \mathfrak{B} , we say the integral

$$J = \int_{a}^{\infty} f(x, y) dx \tag{2}$$

is uniformly convergent in B.

If the uniform convergence of \mathcal{J} breaks down at certain points $\gamma_1, \dots, \gamma_t$ in \mathfrak{B} , we shall say \mathcal{J} is in general uniformly convergent in \mathfrak{B} . Cf. 666.

9 As in Chapters XIII, XIV, we wish now to study the integral 2) with respect to continuity differentiation, and integration We may often simplify our demonstrations without loss of generality by observing that we may write

$$\int_{a}^{a} f dx = \int_{a}^{b} f dx + \int_{b}^{m} f dx = J_{1} + J_{2}$$

Here we may take b so large that none of the lines $x=a_1$ -fall in $(b \infty a \beta)$

The integral J, has been treated in Chapter XIV

10 In this article we have considered f(xy) chiefly with respect to x. Evidently we may interchange x and y which will give us similar definitions with respect to y

We wish also to note that all the following theorems apply to the integral

$$\int_{a}^{a} f(x \ y) dy$$

on interchanging a and y

659 Let f(xy) be regular in R = (a x n R) B finite or infinite Let $\phi(x)$ be integrable in A and

Then
$$|f(xy)| \le \phi(x) \quad \text{in } R$$

$$\int_{-\infty}^{\infty} f(x | y) dx$$
 (1)

18 uniformly convergent in D

For

$$\left| \int_{x}^{x} f dx \right| \leq \int_{x}^{x} |f| dx \qquad \text{by a28}$$

$$\leq \int_{a}^{b} \phi dx$$
 by 526 2

Since ϕ is integrable in $\mathfrak A$ we can take δ so large that

$$\int_{0}^{x} \phi dx < \epsilon$$

for any pair of numbers b b'>b

Hence 1) is uniformly convergent in &

660. 1. Let f(xy) be regular in $R = (a \infty \alpha \beta)$, β finite or infinite.

Let

$$f(x, y) = \phi(x)g(x, y),$$

where, 1° , ϕ is absolutely integrable in \mathfrak{A} . 2° , g(xy) is limited in R and integrable in any (a, b), for each y in \mathfrak{B} .

Then

$$\int_{a}^{x} f(xy) dx \tag{1}$$

is uniformly convergent in B.

For, g being limited in R, let

$$|g(xy)| \leq M$$

By 1°, there exists for each $\epsilon > 0$, a b such that

$$\int_{b'}^{b''} |\phi(x)| dx < \frac{\epsilon}{M}, \qquad b < b' < b''. \tag{2}$$

Then for any y in \mathfrak{B} ,

$$\left| \int_{b'}^{b''} f dx \right| = \left| \int_{b'}^{b''} \phi g dx \right|$$

$$\leq M \int_{b'}^{b''} |\phi| dx, \quad \text{by 529.}$$

$$< \epsilon, \quad \text{by 2).}$$

Hence 1) is uniformly convergent in B.

2. As corollary of 1, we have, by 635:

In $R = (\alpha \infty \alpha \beta)$; $\alpha > 0$, β finite or infinite, let

$$f(xy) = \frac{g(x, y)}{x^{\lambda}}$$
, or $\frac{x^{\mu}g(xy)}{e^{\nu x}}$; $\lambda > 1$, $\nu > 0$.

where g is limited in R, and integrable in any (a, b) for each y in \mathfrak{B} .

Then

$$\int_{0}^{\infty} f(xy) dx$$

is uniformly convergent in B.

468

 Let f(xy) be regular in R = (a x αβ) β finite or infinite Let $f(xy) = \phi(x) f(xy)$

where 1° $\phi(x)$ is integrable in $\mathcal R$ 2° , g(xy) is limited in R and a monotone function of x for any y in B Then

f(xy)dz

is uniformly convergent in B

har by the Second I bearem of the Mean, 545,

$$\int_{b}^{b} \phi g dx = g(b + 0 \ y) \int_{b}^{b} \phi dx + g(b' - 0 \ y) \int_{b}^{a} \phi dx \quad b < b' < \xi < b''$$

But a being limited in R and & integrable, the right side is numerically < e for any y in 29 and any pair of numbers & b'. provided b is taken lurge enough

2 Let f(xy) be regular in R = (axaB) B finite or infinite

 $f(xy) = \sigma(xy)h(xy)$

where 1° h(zy) is limited in R and monotone for each y in B, and 2°

 $\int_{0}^{\infty} g(xy)dx$

is un formly convergent in B Then $\int_{0}^{\infty} f(xy)dx$

is un formly convergent in 91 For by 545

$$\int_{a}^{b} f dx = h(b + 0 \ y) \int_{b}^{a} g dx + h(b'' - 0 \ y) \int_{b}^{y} y dx$$
 (1)

But h being limited in R

On the other hand, by 2° there exists a bo such that each integral on the right of 1) is numerically < \$/2 Wf rang pair of numbers b' b"> h.

Hence for any y in \mathfrak{B} ,

$$\left|\int_{b'}^{b''} f dx\right| < \epsilon.$$

662. Integration by Parts. Let f(xy) be regular in $R = (a \infty \alpha \beta)$, β finite or infinite. The integral

$$J = \int_{a}^{\infty} f(xy) dx$$

is uniformly convergent in B, if

$$\int_{-\infty}^{\infty} f(x,y)dx = F(x,y) + \int_{x}^{\infty} g(x,y)dx; \qquad (1)$$

where both expressions on the right are uniformly evanescent for $x \doteq \infty$.

For then, for each $\epsilon > 0$ there exists a b such that

$$\left| F(x,y) \right| < \frac{\epsilon}{2}, \left| \int_{x}^{x} g dx \right| < \frac{\epsilon}{2},$$
 (2)

for any x > b, and any y in \mathfrak{B} .

Hence 1) and 2) give

$$\left|\int_{x}^{\infty}fdx\right|<\epsilon.$$

663. Examples.

1. The integral

$$\Gamma(y) = \int_0^\infty e^{-x} x^{y-1} dx, \qquad (1)$$

defining the Gamma function, considered in 642, is uniformly convergent in $\mathfrak{B}=(\alpha,\beta), \quad \alpha>0.$

For, consider the singular integral relative to x = 0.

We have, since 0 < x < 1,

$$x^{n-1} \le x^{n-1}$$
, in \mathfrak{B} .

Henee

$$e^{-x}x^{y-1} \leq x^{\alpha-1},$$

Thus, by 612, the singular integral relative to x = 0 is uniformly evanescent in \mathfrak{B} . Consider next the singular integral relative to $x = \infty$. We have, since x > 1,

$$e^{-x}x^{y-1} \gtrsim \frac{x^{\beta-1}}{e^x}$$
, in \mathfrak{B} .

Hence this singular integral is uniformly evanescent in B. Thus 1) is uniformly convergent in B.

$$J = \int \frac{\sin 2y}{2} dx$$

This is uniformly convergent in any Θ ($\alpha \infty$) which does not contain the point y = 0 as may be seen by SS^3 . For integrating by parts

$$\int_{a}^{\infty} \frac{n \, x \, y}{2} \, dx = \left[\frac{\cos x y}{x y} \right]_{a}^{\infty} \int_{a}^{\infty} \frac{\cos x y}{x^{2} y} \, dx$$

$$\frac{\cos x y}{\pi y} \int_{a}^{\infty} \frac{\cos x y}{x^{2} y} \, dx, \qquad (2)$$

To fix the ideas, suppose a > 0 then

This shows that the first term on the right of 2) is an formly evanescent in E. The second term is an formly evanescent by 600 1 as is seen setting

$$\phi(x) = \frac{1}{e^2} \phi(xy) - \frac{\cos xy}{x}$$

For later use let us note that

$$\lim \frac{\cos zy}{zy} = 0 \quad \lim \int_{-\infty}^{\infty} \frac{\cos zy}{z^2} dz = 0.$$

Непов

2

$$\int_0^\infty \frac{1}{x} \frac{e^{-xy}}{e^{xy}} \sin \lambda x \, dx \qquad (3)$$

is a formly convergent $n \in (0 \infty)$ by 651. For in the first place the integrand f(xy) is continuous in $P = (0 \infty 0 \infty)$. For the only possible points of diagonal unit θ on the line x = 0.

But the Law of the Mean sives

Hence for x ≠ 0

$$f(xy)$$
 y sin λx $xy^{2}e^{-2\pi x}\sin \lambda x$, $0 < \theta < 1$

This shows that f is continuous at each point on the y axis, if we give to f the value 0 at these points.

This fact established, we can apply set by setting

$$\phi(z) = \frac{\sin \lambda z}{z} \quad g(zz) = 1 - e^{-zz}$$

Then ϕ is integrable in (0 ∞) by 646 while g as obviously in ted in E and a monotone increasing function of x for each y in B. Hence 3) is no formly convergent in B.

(7

$$\int_0^\infty \frac{\sin xy \cos \lambda x}{x} \, dx \tag{4}$$

is uniformly convergent in $\mathfrak{B} = (0, \infty)$ except at $y = |\lambda|$.

For, in the first place the integrand f(x, y) is continuous in $R = (0 \infty 0 \infty)$ if we give to f the value y at the point (0, y).

For, the Law of the Mean gives

$$\sin xy = xy - \frac{x^2y^2}{2}\sin \theta xy, \qquad 0 < \theta < 1.$$

Hence for $x \neq 0$,

$$f(xy) = y \cos \lambda x - \frac{xy^2}{2} \sin \theta xy \cos \lambda x.$$

Thus

$$\lim_{x=0, h=0} f(x, y+h) = y.$$

This established, we have only to show that the singular integral

$$B = \int_b^b f(xy) dx, \qquad b < b' < b'',$$

is uniformly evanescent in B.

Now by the Second Theorem of the Mean, 545,

$$B = \frac{1}{h'} \int_{b}^{\xi} \sin xy \cos \lambda x \, dx + \frac{1}{h''} \int_{\xi}^{b''} \sin xy \cos \lambda x \, dx. \tag{5}$$

But for $y \neq |\lambda|$,

$$\int \sin xy \cos \lambda x \, dx = -\frac{\cos (y - \lambda)}{2(y - \lambda)} - \frac{\cos (y + \lambda)}{2(y + \lambda)}.$$
 (6)

Let

$$|y-\lambda|, |y+\lambda| > \sigma.$$

Then 6) shows that each of the integrals in 5) is numerically $<2/\sigma$.

Let therefore, $b>4/\epsilon\sigma$; then

$$|B| < \epsilon$$

for any y satisfying 7). That is, B is uniformly evanescent except at $y = |\lambda|$. Hence the integral 4) is uniformly convergent except at this point.

We may arrive at this result more shortly, making use of 2.

For,

$$2\sin xy\cos \lambda x = \sin x(y+\lambda) + \sin x(y-\lambda)$$

Hence

$$\int_0^\infty \frac{\sin xy \cos \lambda x}{x} dx = \int_0^\infty \frac{\sin x (y + \lambda)}{x} dx + \int_0^\infty \frac{\sin x (y - \lambda)}{x} dx.$$

Here the first integral is uniformly convergent, if $y \neq -\lambda$; the second integral is uniformly convergent, if $y \neq \lambda$.

$$\int_0^\infty \frac{x \sin xy}{1+x^2} \, dx$$

is uniformly convergent in (α, ∞) , $\alpha > 0$.

For

$$\frac{x\sin xy}{1+x^2} = \frac{\sin xy}{x} \cdot \frac{1}{1+\frac{1}{x^2}}.$$

We have now only to apply 661, 2, using the result obtained in Ex. 2.

$$\int_{0}^{\infty} \frac{3x^{3} - y}{3x} \sin(x^{3} - xy) dx,$$

We assign the value 0 to the integrand, for x = 0.

To show that this integral is uniformly convergent in any 8 = (a5), let us use the method of 662. If we set

$$u = \frac{1}{3x}, \quad dv = (3x^{2} - y) \sin(x^{2} - 2y),$$

$$\int_{0}^{\infty} u dv = \int_{0}^{\infty} \frac{\cos(x^{2} - 2y)}{3x^{2}} \int_{0}^{\infty} - \int_{0}^{\infty} \frac{\cos(x^{2} - 2y)}{3x^{2}} dx$$

(8

(9

 $= \frac{\cos(x^3 - xy)}{3x^3} - \int_0^x \frac{\cos(x^3 - xy)}{3x^3} dx$

Here both terms are uniformly evanescent to 2 by 660, 2 Hence 8) is uniformly convergent in 8

7
$$\int_{0}^{\infty} \cos(z^{2} - zy) dx$$
We can write
$$\int_{0}^{\infty} \cos(z^{2} - zy) dz = \int_{0}^{\infty} \frac{2z^{2} - y}{z^{2}} \cos(z^{2} - zy) dz + \int_{0}^{\infty} \frac{\cos(z^{2} - zy)}{z^{2}} dz$$

The second integral on the right is uniformly evanescent by 560, 2 The first integral is also uniformly evanescent. For integrating by parts.

$$\int_{0}^{\infty} \frac{3}{2} \frac{z^{2} - y}{2} \cos(z^{2} - zy) dz = -\frac{\sin(z^{2} - zy)}{2} + \frac{2}{2} \int_{0}^{\infty} \frac{\sin(3z^{2} - zy)}{2} dz.$$

Here both terms on the right are obviously uniformly evanescent,

564 Let f(xy) be regular in $R = (a \infty a \beta)$, β finite or infinite Let

$$J = \int_{a}^{a} f(xy) dx$$

converge uniformly in B except possibly at a., a. To establish the uniform convergence of J throughout B, we have only to show that J is uniformly convergent in each of the little intervals

$$\mathfrak{B}_s = (a_s - \delta, a_s + \delta)$$

That is, we have only to show that for each $\epsilon > 0$, and for some δ>0, there exists a δ such that

$$\int f(xy)dx < \epsilon$$

for any y in \mathfrak{B}_s and every $\delta' > \delta_s$, $\kappa = 1, 2 \cdots m$.

665. Examples.

1.

$$J = \int_0^\infty \frac{\sin y \sin xy}{x} \, dx$$

is uniformly convergent in $\mathfrak{B} = (0, \infty)$.

For, in the first place, the integrand f(xy) is continuous in $R = (0, \infty, 0, \infty)$ if we set

$$f(0, y) = y \sin y.$$

We have therefore only to consider the singular integral relative to $x = \infty$, in the intervals $\mathfrak{B}_1 = (0, \delta)$, $\mathfrak{B}_2 = (\delta, \infty)$. Now as in 663, 2, we have for y > 0,

$$K = \int_{x}^{\infty} \frac{\sin y \sin xy}{x} dx = \frac{\sin y \cos xy}{xy} - \sin y \int_{x}^{\infty} \frac{\cos xy}{x^{2}y} dx.$$

The reasoning of 663, 2 shows that K is uniformly evanescent in \mathfrak{B}_2 . As to \mathfrak{B}_1 , we note first that K=0 for y=0. Also that

$$\frac{\sin y}{y} = 1 + \eta', \qquad |\eta'| < \eta,$$

 η being as small as we choose, if δ is taken small enough.

Hence for any y in \mathfrak{B}_1 ,

$$|K| < \frac{1+\eta}{x} + (1+\eta) \int_x^{\infty} \frac{dx}{x^2},$$

which shows that K is uniformly evanescent in B1.

2.

$$\int_0^\infty \frac{\sin xy}{ye^{\lambda x}} \, dx, \qquad \lambda > 0 \tag{1}$$

is uniformly convergent in $\mathfrak{B} = (0, \beta)$.

For, the integrand f(xy) is continuous in $R = (0 \infty 0 \beta)$, if we set

$$f(x_1 \ 0) = \frac{x}{e^{\lambda x}}$$

Let us consider therefore the singular integral relative to $x=\infty$. We set $\mathfrak{B}_1=(0,\,\delta)$, $\mathfrak{B}_2=(\delta,\,\infty)$. Obviously 1) is uniformly convergent in \mathfrak{B}_2 .

To show the same for \mathfrak{B}_1 , we note that

$$\sin xy = xy + \tau x^3y^3, \quad |\tau| < 1,$$

by the Law of the Mean. Hence

$$|f(xy)| \le \frac{x}{e^{\lambda x}} + \frac{x^3 \delta^2}{e^{\lambda x}}, \quad \text{in } (0, \infty, 0, \delta).$$

Thus, by 659, the integral 1) is uniformly convergent in Bi.

Continuity

666 1 Let f(zy) be regular in R = (a ∞ aβ) β finite or infinite. except on the lines x = a, x = a,

1º Let

$$J = \int_{-\infty}^{\infty} f(xy)dx$$

be uniformly convergent in B

 $\lim f(xy) = \phi(x) \qquad \eta \text{ finite or infinite}$ 2º Let

uniformly in any (a, b) except possibly on the lines $x = a_1$

Then

$$j = \lim_{x \to \infty} \int f(x, y) dx$$
 exists (1)

Then

3° Let
$$\phi(x)$$
 be integrable in any $(a \ b)$
Then
$$\lim_{x \to a} J = \lim_{x \to a} \int_{a}^{a} f(xy) dx = \int_{a}^{a} \phi(x) dx \qquad (2$$

By virtue of 616 we may assume that f is regular in R and that

 $f = \phi$ uniformly in any $(a \ b)$ To fix the ideas let n = x

We show first that 3 exists a e for each e>0 there exists a 7 such that

$$D = \int_{a}^{b} |f(x y) - f(x y')| dx$$

is numerically < e for any pair of numbers y' y'' > y Now

$$D = \int_{a}^{b} \{f(xy') - f(xy'')\} dx + \int_{a}^{b} f(xy') dx - \int_{a}^{b} f(xy'') dx$$

$$= D_{1} + D_{3} + D_{4}$$

By 1" there exists a b such that

 $D_{\bullet} = D_{\bullet} | < \epsilon/4$ (3 for any y y in B

By 2° we can take y such that for any x in (a, b)

$$|f(xy)-\phi(x)|<\frac{\varepsilon}{4(b-a)}$$
 $y>\gamma$

(9

Hence

$$|f(x, y')-f(x, y'')|<\frac{\epsilon}{2(b-a)},$$

for any y', $y'' > \gamma$, and x in (a, b).

Thus

$$|D_1| < \epsilon/2. \tag{4}$$

From 3), 4) we have

$$|D| < \epsilon$$
.

We next show that 2) holds; i.e. for each $\epsilon > 0$ there exists a b_0 , such that

 $\left| j - \int_{a}^{b} \phi dx \right| < \epsilon \tag{5}$

for any $b > b_0$.

From 1), there exists a γ such that

$$j = \int_{a}^{\infty} f(xy)dx + \epsilon', \qquad |\epsilon'| < \frac{\epsilon}{3}$$
 (6)

for any $y > \gamma$.

From 1°, there exists a b_0 such that

$$\int_{a}^{x} f(xy) dx = \int_{a}^{b} f(xy) dx + \epsilon^{II}, \qquad |\epsilon^{II}| < \frac{\epsilon}{3} \qquad (7)$$

for any $b > b_0$, and any y in \mathfrak{B} .

From 2°, we can take y large enough so that also

$$f(x, y) = \phi(x) + g(xy), \qquad |g| < \frac{\epsilon}{3(b-a)}$$
 (8)

for any x in (a, b), and any $y > \gamma$.

Hence, by 3°, $\int_a^b f(xy) dx = \int_a^b \phi(x) dx + \epsilon''', \qquad |\epsilon'''| < \frac{\epsilon}{3}$

for any $b > b_0$, and any $y > \gamma$.

From 6), 7), 8), 9) we have

$$j = \int_a^b \phi(x) dx + \epsilon_1 \qquad |\epsilon_1| < \epsilon$$

for any $b > b_0$. But this is 5).

2. The reader should note that the lines $x = a_1, \dots$ on which the uniform convergence of f(xy) to $\phi(x)$ breaks down, are according to 617, 3 singular lines, whether f(xy) has points of infinite discontinuity on them or not. If the integral J is to be uniformly

convergent in B, the singular integrals relative to all these lines must be uniformly evanescent

667 Example As we shall show in 675,

$$J = \int_0^{\infty} \frac{1 - e^{-\alpha}}{2} \operatorname{cla} \lambda x \, dx = \operatorname{arctg} \frac{y}{\lambda}, \quad \lambda \neq 0.$$

The application of 666 gives
$$\lim_{x\to 0} J = \int_0^x \frac{\sin \lambda x}{x} dx = \begin{cases} \pi/2, & \lambda > 0 \\ 0, & \lambda = 0 \\ -\pi/2, & \lambda < 0 \end{cases}$$

That the conditions of Theorem 666 are fulfilled is easily seen For, defining the integrand f(xy) of J as in 663 3, it is continuous in $B = (0, \infty, 0, \infty)$ We also saw that the singular integral relative to z = 10 is uniformly evanescent in 8 = (0, 10) Now

$$\lim_{x \to \infty} f(x,y) = \frac{\sin \lambda x}{x}$$

uniformly in $\mathbb{H} = (0, \infty)$ except at z = 0The line z=0 is therefore a singular line by 617, 3. But

$$\left|\int_{s}^{s} \frac{1-e^{-st}}{s} \sin \lambda x \, dx\right| \le \left|\int_{s}^{s} \frac{\sin \lambda x}{s} \, dx\right| < \epsilon, \quad 0 < \sigma < \delta$$

if a is taken sufficiently small. This singular integral is therefore uniformly stanescent. Hence J is uniformly convergent in B Thus all the conditions of 666 ere saturded.

From 1) we may deduce the following relations

$$\int_{0}^{\infty} \frac{\sin \alpha x \cos \beta z}{x} dx = 0,$$

$$\int_{0}^{\infty} \frac{\cos \alpha x \sin \beta z}{x} dx = \frac{x}{2}.$$
(3)

which may be combined in a surgle formula

$$\int_0^a \frac{\sin \lambda x \cos \mu x}{x} dx = \begin{cases} 0, & 0 \le \lambda < \mu \\ \pi/2, & 0 \le \mu < \lambda. \end{cases}$$

In fact, since $\alpha + \beta > 0$, $\alpha - \beta < 0$, we have from 1).

$$\int_0^\infty \frac{\sin{(x+\beta)x}}{x} dx = \frac{x}{2},\tag{5}$$

$$\int_0^{\pi} \frac{\sin(\pi - \beta)x}{x} dx = -\frac{\pi}{2}$$
 (6)

$$\sin (\alpha + \beta)x + \sin (\alpha - \beta)x = 2 \sin \alpha x \cos \beta x, \qquad (7)$$

$$\sin (\alpha + \beta)x - \sin (\alpha - \beta)x = 2 \cos \alpha x \sin \beta x, \qquad (8)$$

Adding and subtracting 5), 6) and same 7), 8), we get 2), 3)

668. That the relation

$$\lim_{y \to \eta} \int_a^{\infty} f(x, y) dx = \int_a^{\infty} \lim_{y \to \eta} f(x, y) dx \tag{1}$$

is not always true is shown by the following example:

From

$$\int e^{-xy} \sin x \, dx = -\frac{e^{-xy}(\cos x + y \sin x)}{1 + y^2},$$

$$\int_0^\infty \frac{\sin x}{e^{xy}} \, dx = \frac{1}{1 + y^2}.$$
(2)

we have for y > 0,

 $R \lim_{y=0} \int_0^\infty \frac{\sin x}{e^{xy}} dx = 1.$

On the other hand,

$$\int_0^\infty R \lim_{y=0} \frac{\sin x}{e^{xy}} dx = \int_0^\infty \sin x \, dx$$

does not even exist.

Thus the relation 1) does not hold.

669. 1. Let f(xy) be regular in $R = (a \times a\beta)$ except possibly on the lines $x = a_1, \dots x = a_r$.

Let f(xy) be a uniformly continuous function of y in \mathfrak{B} except possibly on the lines $x = a_1, \cdots$ Let

$$J(y) = \int_{a}^{\infty} f(xy) dx$$

be uniformly convergent in B.

Then J is continuous in B.

For, f(x, y + h) converges uniformly to f(x, y), h = 0 in \mathfrak{B} except on the lines $x = a_1, \dots$ We have, therefore, only to apply 666.

2. Let f(xy) be in general regular with respect to x in $R = (a \propto \alpha \beta)$. Let f be in general a semi-uniformly continuous function of y in \mathfrak{B} . Let

$$J(y) = \int_{a}^{x} f(xy) dx$$

be uniformly convergent in B.

Then J is limited in B, and in general a continuous function of y.

For, we can take b so large that

for any y in B On the other hand,

$$\int_{a}^{b} f dx$$

is limited in ${\mathfrak B}$ by 618 1 Hence J is limited in ${\mathfrak B}$ That J is in general continuous in ${\mathfrak B}$ follows from 1

 ${\mathfrak I}$. In this connection let us note the following theorem whose demonstration is obvious

Let f(xy) be regular in $R = (\sigma \times \alpha \beta)$ β finite or infinite, except on the lines $x = a_1$, $y = a_1$ Let

$$\int_{x}^{x} f(xy)dy$$

be uniformly convergent in any (a b) except at a1 a2. Then the points of infinite discontinuity of

$$g(zy) = \int_{z}^{y} f(xy) dy$$
 $y \in \mathfrak{D}$
must be on the lines $x = a$.

670 1 Let f(xy) be regular in $R = (a \times a\beta)$ except on $x = a_1$ $y = a_1$

1. Let fly

converge uniformly in any (a δ) except at $x = a_1$

 $\phi(y) = \int_{-\infty}^{\infty} dx \int_{-\infty}^{\infty} f dy$

converge uniformly in B Then \$\phi\$ is continuous in B

This is a direct application of 666 1 where

$$g(xy) = \int_{-\infty}^{y} f(xy)dy$$

takes the place of f in that theorem

In fact, by 669, 3. g(xy) has no points of infinite discontinuity except on $x = a_1 \cdots$; and is therefore by 2° , regular in R except on these lines.

Also g(x, y + h) converges uniformly in any (a, b) to g(x, y) as $h \doteq 0$, except at $x = a_1 \cdots$; since

$$g(x, y+h) - g(xy) = \int_{y}^{y+h} f dy$$

is uniformly evanescent in (a, b) by 1°.

Thus applying 666, 1, we have

$$\lim_{h \to 0} \phi(y+h) = \lim_{h \to 0} \int_{a}^{\infty} g(x, y+h) dx = \int_{a}^{\infty} \lim_{h \to 0} g(x, y+h) dx$$
$$= \int_{a}^{\infty} dx \int_{a}^{y} f dy = \phi(y).$$

That is, $\phi(y)$ is continuous at y.

2. As a corollary of 1 we have:

Let f(xy) be in general regular with respect to x in $R = (a \infty \alpha \beta)$. Let

 $\phi(y) = \int_{a}^{\infty} dx \int_{a}^{y} f(xy) dy$

converge uniformly in \mathfrak{B} . Then ϕ is continuous in \mathfrak{B} .

Integration and Inversion

671. 1. Let f(xy) be in general regular with respect to x in $R = (a \times \alpha \beta)$. Let f be in general a semi-uniformly continuous function of y in \mathfrak{B} . Let

$$J(y) = \int_{a}^{\infty} f(xy) dx$$

be uniformly convergent in B.

Then J is integrable in \mathfrak{B} .

This follows at once from 500 and 669, 2.

2. As a corollary of 1 we have:

Let f(xy) be simply irregular with respect to x in $R = (a \propto a \beta)$. Let J be uniformly convergent in \mathfrak{B} . Then J is integrable in \mathfrak{B} . 480

672 1 Let f(xy) be in general regular in $R = (a \infty \alpha \beta)$, with respect to x 1º Let

far

be uniformly convergent and integrable in B 2º Let

∫ dy ∫ fdx, b arbitrarily large, admit inversion in B

Then

$$\int_a^y dy \int_a^x f dx = \int_a^\infty dx \int_a^y f dy, \quad \text{in } \mathfrak{B}$$

a

We set
$$\int_{a}^{\infty} f dz = \int_{a}^{a} + \int_{a}^{\infty}$$
 (2)

Since 1) is uniformly convergent in 3 there exists for each .>0 a b. such that Star < -(8

for any y in B and every b>b. Thus 2) 3) give for any win 38

$$\left| \int' dy \int'' f dx - \int'' dy \int'' f dx \right| \le \int \frac{e dx}{c} \stackrel{\text{def}}{=} \stackrel{\text{def}}{=} e$$
(4)

But by 2°.

$$\int_{0}^{\infty}\int_{0}^{\infty}ds = \int_{0}^{\infty}\int_{0}^{\infty}\int_{0}^{\infty}$$

Hence

$$\left|\int_{a}^{r} \int_{a}^{a} - \int_{a}^{s} \int_{a}^{r} \left| \leq \epsilon \qquad b > b_{0},$$
 (5)

which proves the theorem

 Let f(xy) be simply irregular with respect to x in R = (axaβ) Let ∫ fdx

be uniformly convergent in PA

Then

$$\int_{a}^{\beta} dy \int_{a}^{\infty} f dx, \quad \int_{a}^{\infty} dx \int_{a}^{\beta} f dy \tag{6}$$

are convergent and equal.

For, by 671, 2, the integral on the left of 6) exists. Moreover, condition 2° of 1 is fulfilled, by 622, 2.

3. As corollary of 1, we have:

Let f(xy) be in general regular in $R = (a \infty \alpha \beta)$ with respect to x. Let

 $\int_{a}^{\infty} f dx$

be uniformly convergent, and integrable in B.

Let

$$\int_a^y dy \int_a^b f dx, \quad b \text{ arbitrarily large,}$$

admit inversion in B.

Then

$$\int_a^\infty dx \int_a^\nu f(xy) dy$$

is uniformly convergent in B.

This follows at once from 5), since this inequality holds for any y in \mathfrak{B} .

4. From the relation 4) we have also the following corollary, setting $y = \beta$.

Let f(xy) be in general regular in $R = (a \infty \alpha \beta)$ with respect to x. Let

$$\int_a^\infty f dx$$

be uniformly convergent, and integrable in B. Let

$$\int_a^\beta dy \int_a^b f dx, \qquad b \text{ arbitrarily large,}$$

admit inversion. Then

$$\lim_{\infty} \int_a^{\beta} dy \int_a^b f dx = \int_a^{\beta} dy \int_a^{\infty} f dx.$$

5 As a special case of 4 we have, 622, 2 and 571. 2

Let f(xy) be simply irregular with respect to x in $R = (axa\beta)$ Let

$$\int_{x}^{x} f dx$$

be uniformly convergent in B Then

$$\lim_{x \to \infty} \int_{a}^{x} dy \int_{a}^{x} f dx = \int_{a}^{x} dy \int_{a}^{\infty} f dx$$

673 Let f(xy) be regular in R=(axaβ), except on the lines, x=a, x=a, y=a, y=a,

fay faz be convergent and admit intersion in any interval (λ, μ) , which does

not embrace a, a, 2º Let

\int dz \int fdy be a continuous function of y in B

$$K = \int_{a}^{a} dy \int_{a}^{\infty} f dx$$
, $L = \int_{a}^{\infty} dx \int_{a}^{y} f dy$

Then K is convergent and K=L

For simplicity, let $y = \eta$ be the only singular y line, $\alpha < \gamma < \beta$ Then by definition,

$$\int_{a}^{b} dy \int_{a}^{c} f dx = \lim_{n \to \infty} \int_{a}^{n} \int_{a}^{n} + \lim_{n \to \infty} \int_{a}^{b} \int_{a}^{n}.$$

$$(1)$$

$$a < \phi < \gamma, \qquad \gamma < v < \beta$$

Now

Let

$$\int_{a}^{\pi} \int_{a}^{\infty} = \int_{a}^{\infty} \int_{a}^{\infty}, \quad \text{by 1}^{\bullet}. \tag{2}$$

Similarly, $\int_{0}^{3} \int_{0}^{\infty} = \int_{0}^{\infty} \int_{0}^{3} = \int_{0}^{\infty} \int_{0}^{3} - \int_{0$ (3

since L is by 2º, convergent

Now by 2°,

$$\lim_{\alpha} \int_{a}^{\infty} \int_{a}^{u} = \int_{a}^{\infty} \int_{a}^{\gamma}; \tag{4}$$

$$\lim_{n \to \infty} \int_{-\infty}^{\infty} \int_{0}^{v} = \int_{0}^{\infty} \int_{0}^{\gamma} .$$
 (5)

Hence from 2), 4),

$$\lim_{\alpha} \int_{\alpha}^{u} \int_{\alpha}^{\infty} = \int_{\alpha}^{\infty} \int_{\alpha}^{\gamma} ; \qquad (6)$$

also from 3), 5)

$$\lim_{s \to a} \int_{a}^{\beta} \int_{a}^{\infty} = \int_{a}^{\infty} \int_{a}^{\beta} - \int_{a}^{\infty} \int_{a}^{\gamma} = \int_{a}^{\infty} \int_{\gamma}^{\beta}.$$
 (7)

Hence from 1), 6), 7) we have

$$\int_a^\beta \int_a^\infty = \int_a^\infty \int_a^\gamma + \int_a^\infty \int_\gamma^\beta = \int_a^\infty \int_a^\beta.$$

674. 1. Let f(xy) be simply regular in $R = (a \infty \alpha \beta)$, except on the lines $x = a_1, \dots, y = a_1 \dots$

1°. Let

$$\int_{a}^{\infty} f(xy) dx$$

converge uniformly in \mathfrak{B} , except on $y = \alpha_1 \cdots$

2°. Let

$$\int_{a}^{\beta} f(xy) dy$$

converge uniformly in any (a, b), except on $x = a_1 \cdots$

3°. Let

$$\int_{a}^{\infty} dx \int_{a}^{y} f(xy) dy$$

converge uniformly in B.

Let

$$K = \int_{a}^{\beta} dy \int_{a}^{\infty} f dx, \qquad L = \int_{a}^{\infty} dx \int_{a}^{\beta} f dy.$$

Then K is convergent and K=L.

This follows from 673. For, in the first place, condition 1° of 673 is satisfied, by 672, 2.

Secondly, condition 2° of 673 is fulfilled, by 670, 1.

484 INFINITE INTERVAL OF INTEGRATION

2 As a corollary of 1 we have

Let f(xv) be simply irregular with respect to x in R = (axa8) Let

$$\int_{-\infty}^{\infty} f(xy)dx$$

converge in general uniformly in B Let

$$\int dx \int f(xy) dy$$

converge uniformly in B Then

$$\int_{0}^{\infty} dy \int_{0}^{\infty} f dx = \int_{0}^{\infty} dx \int_{0}^{\infty} f dy$$

675 For y > 0 we have from 668 2)

$$\int_0^{\infty} \frac{\sin \lambda x}{e^{xy}} dx - \frac{\lambda}{\lambda^2 + y^2}$$
(1)

The integral on the left does not exist for y - 0 Let us therefore sot

$$f(xy) = \frac{6 \text{ in } \lambda x}{e^{4x}} \qquad y > 0$$

Then integrating 1) from 0 to y we get

$$\int_0^x dy \int_0^x /dz = \int_0^x \frac{\lambda}{\lambda^2 + y^2} dy = \operatorname{arctg} \frac{y}{\lambda} \qquad \lambda \neq 0$$
(2)

We may avert the order of integrat on in 2) by 674 2 For f is continuous in $R = (0 \times 0 v)$ except on the line v = 0 and l m ted in R. It is therefore a mply arregular with respect to g. The pterral 1) obviously converges uniformly in El except at y - 0 The integral

$$\int_{0}^{\infty} dx \int_{0}^{x} f dy = \int_{0}^{\infty} \frac{1 - e^{-xy}}{x} \sin \lambda x dx \qquad (3)$$

is uniformly convergent in 25 by 663 3. Hence the integrals on the left in 2) 3) ace conal and

$$\int_0^{\infty} \frac{1}{x} \sum_{i=1}^{n-1} \sin \lambda x dx - \operatorname{arctg}_{\lambda}^{y} \qquad \lambda \neq 0$$

a

676 We saw in 667 that

676 We saw in 667 that
$$\int_0^{\pi} \frac{v \sin xy}{x} dx - \begin{cases} 0 & y = 0 \\ \frac{\pi}{2} & y > 0 \end{cases}$$
 (1)
Hence integrating between 0 and 1 we get

 $\int_{0}^{1} dy \int_{0}^{\infty} \frac{\sin xy}{x} dx - \frac{y}{x}$ (2 We can invert the order of integration by 674, 2. For, in the first place, the integrand, not being defined in 2), we can make it continuous in $R = (0 \times 01)$, giving it the value y at the points (0, y). Secondly, the integral 1) is uniformly convergent in \mathfrak{B} , except at y = 0, by 663, 2. Finally,

$$\int_0^\infty dx \int_0^x \frac{\sin xy}{x} dy = \int_0^\infty \frac{1 - \cos xy}{x^2} dx$$

is uniformly convergent in B, since

$$\left|\frac{1-\cos xy}{x^2}\right| \leq \frac{2}{x^2}.$$

We can therefore invert in 2), which gives

$$\frac{\pi}{2} = \int_0^\infty \frac{dx}{x} \int_0^1 \sin xy \, dy = \int_0^\infty \frac{1 - \cos x}{x^2} \, dx$$

$$= 2 \int_0^\infty \frac{\sin^2 x/2}{x^2} \, dx = \int_0^\infty \frac{\sin^2 u \, du}{u^2},$$
(3)

setting

x=2u.

Thus 3) gives

$$\int_0^\infty \frac{\sin^2 x \, dx}{x^2} = \frac{\pi}{2} \tag{4}$$

677. That the order of integration can not always be inverted is shown by the following examples.

Ex. 1. Let us consider

$$\int_0^\infty dx \int_0^\beta \cos xy \, dy = \int_0^\infty \frac{\sin \beta x}{x} \, dx$$

$$= \frac{\pi}{2}.$$
(1)

The integral obtained by inverting the order of integration, viz.,

$$\int_0^\beta dy \int_0^\infty \cos xy \, dx$$

does not exist, since

$$\int_0^\infty \cos xy\,dx$$

does not. Inversion in the order of integration in 1) is therefore not permissible

Ex. 2. Let

$$\frac{x^2y^2}{1+x^4y^4} = \frac{u^2}{1+u^4} = \phi(u), \qquad u = xy.$$

Then

$$\frac{\partial \phi}{\partial x} = \frac{\partial \phi}{\partial u} \cdot \frac{\partial u}{\partial x} = y \phi'(u); \qquad \frac{\partial \phi}{\partial u} = x \phi'(u).$$

Let

$$f(x, y) = \phi'(u) = \frac{1}{y} \frac{\partial \phi}{\partial x} = \frac{1}{x} \frac{\partial \phi}{\partial y}$$

We have also

φ(x) = 1 x ψ (x).

 $\phi(w) = \operatorname{arctr} u^2$ where

Thus $\frac{\partial f}{\partial x} \sim \frac{\partial f}{\partial x} \frac{\partial u}{\partial x} = y_{r'}(u)$

and bence

$$\frac{1}{2}\frac{\phi(u)}{z} - \frac{\partial \varphi}{\partial z}$$

Hence $\int_{0}^{\infty} dx \int_{0}^{\infty} f(x,y) dy = \int_{0}^{\infty} dy = \int_{0}^{\infty} \phi(x) dx$ $-\frac{1}{2}\int_{0}^{\infty} \frac{\partial F}{\partial x} dx - \frac{1}{2} \left[\phi(x) \right]_{0}^{\infty} dx$

On the other hand

$$\int_{a}^{y} dy \int_{a}^{\infty} f(x,y) dx - \int_{a}^{\infty} \frac{dy}{y} \int_{a}^{\infty} \frac{\partial \phi}{\partial x} dx - \int_{a}^{\infty} \frac{dy}{y} \left[\phi(x) \right]_{a}^{\infty} = 0.$$

Thus it is not permissible to invert the order of integration in

$$\int_{0}^{\infty} dx \int_{0}^{x} f(x, y) dy = \int_{0}^{\infty} dx \int_{0}^{x} \frac{\partial}{\partial y} \frac{xy^{3}}{1 + x^{2}y^{2}} dy \qquad (2)$$

678 1 Let f(xy) be regular in R = (ax ax), except on the lines $x = a_1$, $y = a_1$ 1° Let

be uniformly convergent in B 2º Let

$$\phi(x) = \int_{a}^{x} f dy$$

be uniformly convergent in any (a b) except at an an , and inte grable in (a b) Then f dx fdy exists,

and

$$\lim_{x \to \infty} \int_{a}^{\infty} dx \int_{a}^{\infty} f dy = \int_{a}^{\infty} dx \int_{a}^{\infty} f dy \tag{1}$$

This is a direct application of 666, 1, the function

$$g(xy) = \int_{-\infty}^{x} f(xy) dy$$

taking the place of f(xy) in that theorem For, in the first place, g has no points of infinite discontinuity, except on the lines $x = a_1$,

..., by 669, 3. Moreover, g(xy) is integrable in \mathfrak{A} , by 1°. Hence g(xy) is regular in R, except on the lines $x = a_1, \dots$

Secondly,

$$\int_a^{\infty} g(xy) dx$$

is uniformly convergent in B, by 1°.

Finally

$$\lim_{y=\infty} g(xy) = \int_a^\infty f dy = \phi(x),$$

uniformly in any (a, b), except on the lines $x = a_1, \dots$; moreover ϕ is integrable in (a, b). Thus all the conditions of 666, 1 are satisfied, and the present theorem is established.

2. As a corollary of 1 we have:

Let f(xy) be simply irregular with respect to y in $R = (a \infty a \infty)$.

Let

$$\int_a^{\infty} dx \int_a^y f dy$$

be uniformly convergent in B. Let

$$\int_{\pi}^{\infty} f dy \tag{2}$$

be uniformly convergent in any (a, b). Then

$$\lim_{n \to \infty} \int_a^{\infty} dx \int_a^y f dy = \int_a^{\infty} dx \int_a^{\infty} f dy.$$

For 2) is integrable in any (a, b), by 671, 2; on interchanging x and y in that theorem.

679. If the conditions of 678 are not satisfied, the relation

$$\lim_{y \to \infty} \int_{a}^{\infty} dx \int_{a}^{y} f dy = \int_{a}^{\infty} dx \int_{a}^{\infty} f dy \tag{1}$$

may be untrue.

Consider, for example,

$$J = \int_{a}^{\infty} dx \int_{0}^{y} \cos xy \, dy, \qquad a > 0.$$
$$= \int_{a}^{\infty} \frac{\sin xy}{x} \, dx.$$

Hero hm J =

On the other hand, the integral

$$\int_a^{\infty} dx \int_a^{\infty} \cos xy \, dy$$

does not even exist, since

does not. Thus the relation 1) in this case as not true

680 1 Let f(xy) be simply regular in $R = (a \infty a \infty)$, except on the lines $x = a_p$, , $y = a_p$

1º Let

$$\int_{a}^{a} f dx$$

be uniformly convergent in any (a, β) except at a₁, ... 2° Let

be uniformly convergent in any (a, b) except at $a_1 \cdots$, moreover let it be integrable in (a, b)

3º Let

$$\int_{-\infty}^{\infty} dx \int_{-\infty}^{\infty} f dy$$

be uniformly convergent in B

Then

are conversent and coual

For, by 674, 1,

$$\int_{a}^{b} dy \int_{a}^{a} f dx = \int_{a}^{a} dx \int_{a}^{a} f dy$$

But by 678, 1, we may pass to the limit $\beta = \infty$, which proves the theorem

2 Let f(xy) be simply regular with respect to y in $R = (a \infty a \infty)$, except on the lines $y = a_1$,

 $\int f dz$

be uniformly convergent in any (α, β) except at α_1, \cdots

Let

$$\int_a^{\infty} f dy$$

be uniformly convergent in any (a, b).

Let

$$\int_{a}^{x} dx \int_{a}^{y} f dy$$

be uniformly convergent in B.

Then

$$\int_a^\infty dy \int_a^\infty f dx, \qquad \int_a^\infty dx \int_a^\infty f dy$$

are convergent, and equal

This follows as in 1, by 674, 1, and 678, 2.

3. Let $f(x, y) \ge 0$ be simply regular in $R = (a \infty a \infty)$ except on the lines $x = a_1, \dots; y = a_1, \dots$

Let

$$\int_{a}^{\infty} f dx$$

be uniformly convergent in any (α, β) except at α_1, \dots

Let

$$\int_{a}^{\infty} f dy$$

be uniformly convergent in any (a, b) except at a, ...

Let

$$L = \int_{a}^{\infty} dx \int_{a}^{\infty} f dy$$

be convergent. Then

$$K = \int_{a}^{\infty} dy \int_{a}^{\infty} f dx$$

is convergent, and K=L.

This is a corollary of 1. For, condition 2° is satisfied since L exists. That condition 3° is fulfilled follows from the fact that the singular integrals of $\int_{-\infty}^{\infty} \int_{-\infty}^{\nu}$

are \leq the corresponding integrals of L since $f \geq 0$.

681 1 We saw in 667 1) that

$$J = \int_0^\infty \frac{\sin xy \cos \lambda x}{x} dx = \begin{cases} 0 & y < \lambda, \\ y/2, y > \lambda, \end{cases} \quad \lambda \quad y \ge 0$$

Multiply by e er and integrate p>0 Then

$$K = \int_0^{\infty} dy \int_0^{\infty} \frac{\sin xy \cos \lambda x}{x \cos \lambda} dx = \int_0^{\infty} J_L \cos ky + \int_0^{\lambda} + \int_{\lambda}^{\infty} - \frac{1}{2} \int_{\lambda}^{\infty} \xi \sin ky dy$$

$$\approx \frac{\pi}{2 - \lambda + \lambda}$$

We can invert the order of integration in 1) by 680 2 For in the first place

$$f(xy) = \frac{x \text{ n } xy \cos \lambda x}{x \cos \lambda}$$

is a unply regular in R = (0x0x) if we set

$$f(0 y) = \frac{y}{e^{-x}}$$

Secondly

F nally

For

490

$$\int_{0}^{\infty} f dz = e^{-\alpha z} \int_{0}^{\infty} \frac{\sin \pi y \cos \lambda z}{z} dz$$

is un formly convergent in B _ (0 x) except for y - \lambda by 663 Ex 4.
Thirdly

$$\int_0^z f y = \cos \lambda x \int_0^\infty \frac{4i \times xy}{xc^2} dy \quad \text{for } x > 0$$

$$\int_0^\infty \frac{y}{xc} dy \quad \text{for } x = 0$$

is un formly convergent n any (0 b) by 680 fig. 2

$$Y = \int dx \int dy = \int dx \int r \sin xy \cos \lambda x dy$$

is no formly convergent n &

$$\int_0^{xh} \frac{n \, xy}{csx} \, dy - \left[- e^{-y_0} \frac{s \, hm \, xy + x \cos xy}{s^2 + s^2} \right]^s$$

Hence $Y = \int_{0}^{\infty} \frac{\cos \lambda x}{\mu^{2} + x^{2}} (1 - e^{-\mu x \cos xy}) dx - \mu e^{-\mu x} \int_{0}^{\infty} \frac{\sin xy}{x} \frac{\cos \lambda x}{\mu^{2} + x^{2}} dx$

$$=Y_1+Y_2$$

II, I2 are uniformly convergent in B by 650. For,

$$\left|\frac{\cos \lambda x}{\mu^2 + x^2} (1 - e^{-\mu y} \cos xy)\right| \le \frac{2}{\mu^2 + x^2},$$

$$\left|\frac{\sin xy}{x} \frac{\cos \lambda x}{\mu^2 + x^2}\right| \le \frac{1}{\mu^2 + x^2}.$$

Thus all the conditions of 680, 2 are satisfied. Inverting therefore in 1), we get

$$K = \int_0^\infty \frac{\cos \lambda x}{x} \, dx \int_0^\infty \frac{\sin xy}{e^{\mu y}} \, dy$$

$$= \int_0^\infty \frac{\cos \lambda x}{x} \, dx \left[-e^{-\mu y} \frac{\mu \sin xy + x \cos xy}{\mu^2 + x^2} \right]_0^\infty$$

$$= \int_0^\infty \frac{\cos \lambda x}{\mu^2 + x^2} \, dx.$$

Comparing with 1), we get

$$\int_0^\infty \frac{\cos \lambda x}{\mu^2 + x^2} dx = \frac{\pi}{2 \mu e^{\lambda \mu}} \qquad \lambda \stackrel{>}{>} 0, \ \mu > 0.$$
 (2)

2. Let us integrate 2) with respect to \(\lambda\). We get

$$\int_0^{\lambda} d\lambda \int_0^{\infty} \frac{\cos \lambda x}{\mu^2 + x^2} dx = \frac{\pi}{2\mu} \int_0^{\lambda} e^{-\lambda \mu} d\lambda$$
$$= \frac{\pi}{2\mu^2} (1 - e^{-\lambda \mu}). \tag{3}$$

We can invert the order of integration in the integral on the left, by 674, 2. For.

$$\int_0^\infty \frac{\cos \lambda x}{\mu^2 + x^2} \, dx$$

is uniformly convergent by 659, since

$$\left|\frac{\cos \lambda x}{\mu^2 + x^2}\right| \leq \frac{1}{\mu^2 + x^2}.$$

In the second place,

$$\int_0^\infty \frac{dx}{\mu^2 + x^2} \int_0^\lambda \cos \lambda x \, d\lambda = \int_0^\infty \frac{\sin \lambda x}{x(\mu^2 + x^2)} \, dx$$

converges uniformly in any interval $(0, \beta)$ by 661, 2 and 663, Ex. 2. Inverting therefore in 3), we get

$$\int_0^\infty \frac{\sin xy}{x(\mu^2 + x^2)} \, dx = \frac{\pi}{2\mu^2} (1 - e^{-\mu y}). \qquad \mu > 0, \, y \stackrel{>}{>} 0.$$

682. Let us evaluate

$$J = \int_0^\infty \frac{dx}{e^{x^2}}$$

which is convergent by 635 3.

We change the variable setting

Then

$$J = \left(\begin{array}{c} y \, dx \\ \end{array} \right)$$

Multiplying by e-y' and integrating we get

This relation is true for any $\alpha > 0$ by 2) Passing to the lim t a - 0 we have, since the I m to exist.

We may suvert the order of integration in the integral on the right by 630 2. For in the first place the integrand is regular and continuous in R ... (0,000) Secondly

is uniformly convergent in any (a, β) a > 0 by 659 since

Thirdly

is nationally convergent in A - (0,0) by 650 since

Finally

$$L = \int_{0}^{z} dx \int_{0}^{z} \frac{q \, dy}{e^{y(1+y^2)}} = \int_{0}^{z} dx \left[-\frac{e^{-y(1+y^2)}}{2(1+x^2)} \right]_{0}^{z}$$

$$= \frac{1}{2} \int_{0}^{z} \frac{dx}{1+x^2} = \frac{z}{4}$$

is convergent. Thus all the cond tions of 680 3 being fulfilled, we can invert in 31. which gives

J* L =/1. Hence

Here we must take the positive sign, a nee the integral 1) is positive by 649 3. Hence, finally

$$\int_{-\infty}^{\infty} \frac{dz}{z} - \frac{\sqrt{z}}{z}$$

Differentiation

683. 1. Let f(xy), $f_y^l(xy)$ be in general regular with respect to x, y in $R = (a \times a\beta)$.

1°. For each x in $\mathfrak A$ let f be continuous in y, while f'_y is in general continuous in y.

2°. For each y in B, let

$$\int_a^b dx \int_a^y f_y^l dy, \qquad b \text{ arbitrarily large},$$

admit inversion. Then

$$\frac{d}{dy} \int_{a}^{\infty} f(xy) dx = \frac{d}{dy} \lim_{b \to \infty} \int_{a}^{y} dy \int_{a}^{b} f'_{y} dx, \qquad (1)$$

provided the derivative on either side exists.

For, by 605,

$$\int_a^y f_y' dy = f(x, y) - f(x, \alpha).$$

Hence

$$\int_{a}^{b} f dx = \int_{a}^{b} dx \int_{a}^{y} f'_{y} dy + \int_{a}^{b} f(x, \alpha) dx$$
$$= \int_{a}^{y} dy \int_{a}^{b} f'_{y} dx + \int_{a}^{b} f(x, \alpha) dx;$$

and therefore

$$\int_{a}^{\infty} f dx = \lim_{b = \infty} \int_{a}^{y} dy \int_{a}^{b} f'_{y} dx + \int_{a}^{\infty} f(x, \alpha) dx.$$

Differentiating, we get 1), since the last term on the right is a constant.

2. As corollary of 1 we have:

Let f(xy) be regular in $R = (a \infty u \beta)$ except on the lines $x = a_1, \dots$ and continuous with respect to y for each x in \mathfrak{A} .

Let f'_y be regular in R except on the lines $x = a_1, \dots$ and uniformly continuous in y, except on these lines.

Let

$$\int_a^\infty f_y' dx$$

be uniformly convergent in B.

Then

$$\frac{d}{dy}\int_{a}^{\infty}f(xy)dx=\int_{a}^{\infty}f'_{y}dx.$$

For, condition 2° of 1 is fulfilled by 622, 2. Hence by 1),

494

$$\frac{d}{dy} \int_{a}^{b} f(xy) dx = \frac{d}{dy} \lim_{n \to \infty} \int_{a}^{b} dy \int_{a}^{b} f_{n}^{*} dx$$

$$= \frac{d}{dy} \int_{a}^{b} f_{n}^{*} dy \int_{a}^{b} f_{n}^{*} dx, \quad \text{by 672, 4, and 671, 2,}$$

$$= \int_{a}^{b} f_{n}^{*} dx, \quad \text{by 669, 1.}$$

684 1 When

$$\int_{a}^{a} f_{x}^{d} dx$$

is not convergent, the following theorem may serve

Let f(xy) be in general regular in $R = (a \times a\beta)$, and continuous with respect to y for each x in A

Let f, be simply irregular with respect to z in R

1º Let

be uniformly contergent in B

2º For any b let

$$\int_{a}^{b} f_{x}^{d} dz = \int_{a}^{b} g(xy)dz + h(b, y), \quad \text{where}$$

 δ^{\bullet} g(xy) is simply irregular in R with respect to x and

$$\int g(xy)dx$$

18 uniformly convergent in B

4° Then

$$\lim_{b \to 0} \int_a^y h(b, y) dy = 0$$

 $J' = \frac{d}{dy} \int_{\bullet}^{\bullet} f(xy) dz = \int_{\bullet}^{\bullet} g(xy) dz$

a

2. As corollary we have:

Let f(xy) be regular in $R = (a \infty \alpha \beta)$, and continuous with respect to y for each x in \mathfrak{A} . Let f'_y be continuous in R. For any b, let

$$\int_a^b f_y^i dx = \int_a^b g(xy) dx + h(b, y),$$

where g is regular in R, and

$$\int_a^\infty g(xy)dx$$

is uniformly convergent in B; also

$$\lim_{b\to\infty}\int_a^y h(b, y)dy=0.$$

Then

$$\frac{d}{dy}\int_{a}^{\infty}f(xy)dx = \int_{a}^{\infty}g(xy)dx.$$

For, condition 1° of 683 is obviously satisfied, while condition 2° is fulfilled by 672, 2. Hence

$$J' = \frac{d}{dy} \lim_{b \to \infty} \int_a^y dy \int_a^b f_y' dx.$$

But

$$\int_a^y dy \int_a^b f_y^i dx = \int_a^y dy \int_a^b y dx + \int_a^y h dy, \quad \text{by } 2^\circ.$$

Hence by 4°,

$$J' = \frac{d}{dy} \text{ in } \int_{a}^{y} dy \int_{a}^{b} y dx$$
$$= \frac{d}{dy} \int_{a}^{y} dx \int_{a}^{\infty} y dx, \quad \text{by 3°,}$$
$$= \int_{a}^{\infty} y dx, \quad \text{which is 1).}$$

EXAMPLES

685. 1. Let

$$J = \int_0^\infty \frac{\sin xy}{xe^x} dx,\tag{1}$$

We show that

$$\frac{dJ}{dy} = \int_0^\infty \frac{\cos xy}{e^x} \, dx, \qquad y \text{ arbitrary,} \tag{2}$$

using 683, 2. For, in the first place, the integrand f(xy) is continuous in $R = (0 \pm \alpha \beta)$, if we set f(0, y) = y.

Obviously J is convergent in 20, by 635, 3

Secondly

f = 008 27

is continuous in R , and

is uniformly convergent in 35, by 660, 2 Thus 683, 2 gives 2) By means of 2) we can evaluate 1)

For obviously,

$$\int_0^\infty \frac{\cos xy}{e^x} dx = \frac{1}{1+y^2}$$

Hence integrating 2), we get

$$J = \int \frac{dy}{1+y^2} = 2\pi c \operatorname{tg} y + C.$$

Since J = 0, for u = 0, we have C = 0 Hence

(\$

6

16

2 From this integral we can also show that

$$\int_0^\infty \frac{\sin xy}{x} dx = \frac{\pi}{2}, \quad y > 0,$$

a result obtained in 667, by the aid of 675. For, set,

$$x = \frac{b}{c}, \quad y > 0,$$

in 3), we get

We now apply 666, 1, letting y = = This is permissible, since

in (0, so) except for s = 0 The integrand f(s, y) is continuous in $R = (0 \infty a \infty)$, if we set

$$f(\theta, y) = 1$$

The only engular line is therefore u = 0 Obviously the shortlar integral for this line, as well as for the line u = eo, is

uniformly evanescent by 615 and 659 Hence passing to the limit, a = a in 5), we get

(sin w dw = w

If we set u = xy, y > 0, we get 4)

$$J = \int_0^\infty \frac{1 - \cos xy}{xe^x} dx. \tag{1}$$

Applying 683, 2, we get

$$\frac{dJ}{dy} = \int_0^\infty \frac{\sin xy}{e^x} dx = \frac{y}{1+y^2}, \quad y \text{ arbitrary.}$$
 (2)

In fact, the integrand f(x, y) is continuous in $R = (0 \infty \alpha \beta)$, if we set

$$f(0, y) = 0,$$

while J is convergent, by 635, 3.

Moreover

$$f_y' = \frac{\sin xy}{e^x}$$

is continuous in R, and

$$\int_0^\infty \frac{\sin xy}{e^x} \, dx$$

is uniformly convergent in B, by 660, 2. This establishes 2).

As in 685, we can use 2) to evaluate 1).

For, integrating 2), we get

$$J = \int \frac{y \, dy}{1 + y^2} = \frac{1}{2} \log (1 + y^2) + C.$$

Here C=0, since J=0 for y=0, by 1).

Thus

$$\int_0^\infty \frac{1 - \cos xy}{xe^x} \, dx = \frac{1}{2} \log (1 + y^2).$$

687. Let us evaluate Fourier's Integral

$$J = \int_0^\infty \frac{\cos 2xy}{e^{x^2}} dx. \tag{1}$$

Using 683, 2, we get

$$\frac{dJ}{dy} = -2\int_0^\infty \frac{x \sin 2xy}{e^{x^2}} dx = K.$$
 (2)

For, the integral 1) is convergent by 635, 2; while the integral 2) is uniformly convergent in any $(\alpha\beta)$, by 660, 2.

In 2), let us integrate by parts, setting

$$u = \sin 2 xy$$
, $dv = -2 xe^{-x^2}dx$,

Then

$$K = uv \int_0^\infty - \int_0^\infty v \, du$$

$$=-2y\int_0^{\infty}e^{-x^2}\cos 2xy\,dx=-2yJ.$$

This in 2) gives, since $J \neq 0$,

$$\frac{dJ}{J} = -2 y dy.$$

Hence
$$\log J = -y^{0} + C$$

by 682 4) Hence 1) 3) 4) give

$$C - \log \sqrt{r}/2$$

$$\int \frac{\cos 2\pi r}{r} dr - \frac{\sqrt{r}}{r} e^{-r}$$

688 In 681 2) we found

$$\int_{0}^{\infty} \frac{\cos xy}{\omega + x^2} dx = \frac{\pi}{2 \cos x} \qquad \mu > 0 \qquad y \le \alpha > 0 \qquad (1)$$

18

14

(1

We can differentiate upder the integral sign by 683, 2 For denoting the nie grand by f(xy) we have

$$f_{\tau}(xy) = -\frac{x \cdot n \cdot xy}{\mu^2 + x^2}$$

which is continuous in $B = (0 \pi a \beta)$

Also

$$\int_{0}^{\infty} f_{x} dx = \int_{0}^{\infty} \frac{n \, xy}{2} \, \frac{dx}{1 + \frac{\lambda^{3}}{x^{3}}}$$

is uniformly convergent in (8 by 661 2 Hence differentiating 1) we get

$$\int_0^\infty \frac{x \sin xy}{\mu^2 + x^2} dx \quad \frac{x}{2} e^{-\mu x} \qquad \mu \quad y > 0$$

689 In 682 4) let us replace z by zył y>0 We gei

the fart of percut wes angles the merbies mile all out's feer of

$$\int_{0}^{\infty} x^{3}e^{-yx^{2}}dx = \frac{\sqrt{x}}{4}y^{-\frac{3}{4}}$$
(2)

In fact the integral on the left of 2) is an formly convergent $n \otimes (a, \beta)$ since

We may now outly different ate 1) at mes which gives

$$\int_{0}^{\infty} x^{2} e^{-x^{2}} dx \frac{\sqrt{e}}{2} \frac{1}{2} \frac{3}{2} \frac{2\pi}{2} \frac{1}{2} y^{2}, \quad y > 0$$

690. Fresnel's Integrals.

Let us start with the relation 689, 1),

$$\int_{0}^{\infty} e^{-yz^{2}} dx = \frac{\sqrt{\pi}}{2} y^{-\frac{1}{2}}, \quad y > 0.$$
 (1)

Let

$$f(xy) = \frac{\sin y}{e^{yx^2}}, \quad \text{for } x > 0;$$

$$=0$$
, for $x=0$.

Then

$$J = \int_0^\infty dy \int_0^\infty f dx = \int_0^\infty dy \int_0^\infty \frac{\sin y}{e^{x^2 y}} dx = \frac{\sqrt{\pi}}{2} \int_0^\infty \frac{\sin y}{\sqrt{y}} dy, \tag{2}$$

since the integral on the right is convergent, by 646. We can invert the order of integration here, by 680, 1. For, f(xy) is continuous in $R = (0\infty0\infty)$, except on the line x = 0. It has, moreover, no point of infinite discontinuity in R. The integral

$$\int_0^\infty f dx = \int_0^\infty \frac{\sin y}{e^{x y}} dx$$

is uniformly convergent in any $(0, \beta)$ except at y = 0. The integral

$$\int_0^\infty f dy = \int_0^\infty \frac{\sin y}{e^{x^2 y}} \, dy, \qquad x > 0.$$

is uniformly convergent in any (0, b), except at x = 0. Finally,

$$Y = \int_0^\infty dx \int_0^y f dy$$

is uniformly convergent in B. For

$$\int_0^y J dy = \left[-\frac{x^2 \sin y + \cos y}{(1 + x^4)e^{x^2y}} \right]_0^y.$$
 (3)

Hence

$$Y = \int_0^\infty \frac{dx}{1+x^4} - \int_0^\infty \frac{x^2 \sin y + \cos y}{(1+x^4)e^{x^2y}} dx = Y_1 - Y_2.$$

Here Y_2 is uniformly convergent in \mathfrak{B} , since it is independent of y. Likewise Y_2 is uniformly convergent, since its integrand is numerically

$$\leq \frac{1+x^2}{1+x^4}.$$

Thus all the conditions of 680, 1 being fulfilled, we can invert the order of integration in 2), which gives

$$J = \int_0^\infty dx \int_0^\infty f dy$$
$$= \int_0^\infty \frac{dx}{1 + x^4},$$
 (4)

as is seen from 3), on passing to the limit $y = \infty$. But

$$\int_0^{\infty} \frac{dx}{1+x^4} = \frac{\pi}{4} \frac{1}{\sin \pi/4} = \frac{\pi}{2\sqrt{2}}.$$

Thus by 2) 4) gives

$$\int_0^\infty \frac{\sin y}{\sqrt{y}} \, dy = \frac{\sqrt{y}}{\sqrt{2}}$$

If instead of multiplying 1) by s n y we had multiplied by cos y we would have got by the same reasoning

$$\int_{0}^{\infty} \frac{\cos y}{\sqrt{s}} dy = \frac{\sqrt{y}}{\sqrt{s}}$$
(6)

The integrals 5) 6) are known as Fresnel's integrals They occur in the Theory of Light.

If we set y = z2 these integrals give

$$\int_0^z \sin x^t dx - \int_0^z \cos x^t dx \approx \frac{1}{2} \sqrt{\pi/2}.$$

691 1 Let us show that S.oke a Integral

$$S = \int_0^1 \cos(x^0 - xy) dx$$
 (1

satisfies the relation

500

$$\frac{d^2S}{dy^2} + \frac{1}{3}yS = 0 (2$$

This fact will enable us to compute S by means of an infinite series. We have in the first place

$$\frac{dS}{dy} = \int_0^x z \sin(z^2 - zy)dz \qquad (3)$$

by 683–2 a nee the integral 3) as un formly convergent in any $E=(a,\beta)$. In fact using the transformation of the variable employed in 667

$$u = x(x^0 - y) \tag{4}$$

we bave

$$\int_0^a z = u \left(x^0 - xy \right) dx - \int_0^a \frac{x \in u \times du}{3x^2 - y}$$

where b care corresponding values in 4)

B t $\frac{3 \times 5}{3 \times 5} = \frac{3 \times 5}{3 \times 5} = \frac{3 \times 5}{3 \times 5} = \phi(u)g(u \ y)$

We can now apply 661 I replacing x in that theorem by u. Thus there exists a control that

But then the relation 4) shows that there exists a B such that

for any b > B and for any y in B Hence the integral 3) is uniformly convergent.

To find the second derivative of S, we cannot apply 683 to the integral 3). For

$$\int_0^\infty x^2 \cos{(x^3 - xy)} dx$$

is not even convergent, as we saw 657.

We may, however, apply 684, 2. In fact,

$$\int_0^b x^2 \cos(x^3 - xy) dx = \int_0^b \frac{3x^2 - y}{3} \cos(x^3 - xy) dx + \frac{y}{3} \int_0^b \cos(x^3 - xy) dx$$

$$= \frac{1}{3} \left[\sin(x^3 - xy) \right]_0^b + Y$$

$$= \frac{1}{3} \sin(b^3 - by) + Y.$$

$$\int_0^\infty \cos(x^3 - xy) dx$$

But

is uniformly convergent, as we saw 663, 7.

On the other hand,

$$\int_a^y \sin(b^3 - by) dy = \frac{\cos(b^3 - by) - \cos(b^3 - b\alpha)}{b},$$

which ± 0 as $b \pm \infty$. Thus 684, 2 gives

$$\frac{d}{dy} \int_0^\infty x \sin(x^3 - xy) dx = \frac{-y}{3} \int_0^\infty \cos(x^3 - xy) dx.$$
 (5)

From 1), 3), 5) we have 2).

2. Before leaving this subject, let us show the uniform convergence of the integral 3), by another method.

From the identity

$$x = \frac{3x^2 - y}{3x} + \frac{y}{3} \frac{3x^2 - y}{3x^3} + \frac{y^2}{9x^3},$$

we have

$$\int_{b}^{\infty} x \sin(x^{3} - xy) dx = \int_{b}^{\infty} \frac{3x^{2} - y}{3x} \sin(x^{3} - xy) dx + \frac{y}{3} \int_{b}^{\infty} \frac{3x^{2} - y}{3x^{3}} \sin(x^{3} - xy) dx + \frac{y^{2}}{9} \int_{b}^{\infty} \frac{\sin(x^{3} - xy)}{x^{3}} dx = T_{1} + T_{2} + T_{3}.$$

Obviously T_3 is uniformly convergent by 660, 2.

That T_1 is uniformly convergent, was shown in 663, 6. That T_2 is uniformly convergent, follows from 661, 2; since T_1 is uniformly convergent.

Elementary Properties of B(u, v), $\Gamma(u)$

692. 1. In 641 we saw

$$B(u, v) = \int_0^{\infty} \frac{x^{u-1} dx}{(1+x)^{u+v}}$$
 (1)

is a one-valued function whose domain of definition is the first quadrant in the u-, v-plane, points on the u-, v-axes excepted.

In 642 we saw

502

$$\Gamma(u) = \int_{0}^{\infty} e^{-x} x^{n-1} dx \qquad (2)$$

is a one valued function whose domain of definition is the positive half of the u axis the origin excepted. We wish to deduce here a few of the elementary properties of these functions

2 By a change of variable the integrals 1), 2) take on various Thus in 1) set

$$x = \frac{y}{1-y}$$

We get If we set hera

e get
$$B(u, v) = \int_{v}^{1} y^{v-1} (1-y)^{v-1} dy \qquad (3)$$
 we set here
$$v = 1-z$$

we get

$$B(u, v) = \int_{-\infty}^{1} z^{n-1} (1-z)^{n-1} dz \qquad (4)$$

In 3) let us set $y = \sin^2 \theta$ we get

$$B(u \ v) = 2 \int_{-\pi}^{\pi} \sin^{2} v \ 1 \theta \cos^{4v-1} \theta d\theta \qquad (5)$$

If we set

For,

$$x = \log 1/y$$

in 2) we get $\Gamma(u) = \int_{u}^{1} \log \left(\frac{1}{u}\right)^{u-1} dy$

8 We establish now a few relations for the B functions Ĭn the first place the comparison of 3) 4) gives

$$B(u \ v) = B(v \ u) \tag{7}$$

(6

which shows that B is symmetric in both its arguments As addition formulæ we have the three following 8) 9) 10)

$$B(u+1 v) + B(u v+1) = B(u v)$$
 (8)

 $B(u \ v) = \int_{-1}^{1} x^{u-1} (1-x)^{u} (1-x+x) dx$

$$= \int_{a}^{1} x^{*} (1-x)^{*-1} dx + \int_{a}^{1} x^{*-1} (1-x)^{*} dx$$

which is 8) $vB(u+1 \ v) = uB(u \ v+1)$ (9

For,
$$B(u+1, v) = \int_0^1 x^u (1-x)^{v-1} dx;$$
 integrating by parts,
$$= \left[-\frac{x^u (1-x)^v}{v} \right]_0^1 + \frac{u}{v} \int_0^1 x^{u-1} (1-x)^v dx$$
$$= \frac{u}{v} B(u, v+1),$$

which is 9).

From 8), 9) we have

$$B(u, v) = \frac{u+v}{v} B(u, v+1) = \frac{u+v}{u} B(u+1, v).$$
 (10)

We can show now that B(u, n) = B(n, u) is a rational function of u, viz.: B(u, 1) = 1/u. (11

$$B(u, n) = \frac{1}{u} \cdot \frac{1}{u+1} \cdot \frac{2}{u+2} \cdot \dots \cdot \frac{n-1}{u+n-1}.$$
 (12)

For.

$$B(u, 1) = \int_0^1 x^{u-1} dx = \left[\frac{x^u}{u} \right]_0^1 = \frac{1}{u},$$

which proves 11). From this we get 12), using 10).

4. We establish now a few relations for the Γ function.

$$\Gamma(u+1) = u\Gamma(u). \tag{13}$$

For, integrating by parts,

$$\Gamma(u+1) = \int_0^\infty x^u e^{-x} dx = \left[-e^{-x} x^u \right]_0^\infty + u \int_0^\infty e^{-x} x^{u-1} dx$$
$$= u \int_0^\infty e^{-x} x^{u-1} dx.$$

We observe next that

$$\Gamma(1) = 1. \tag{14}$$

For.

$$\Gamma(1) = \int_0^\infty e^{-x} dx = \left[-e^{-x} \right]_0^\infty = 1.$$

From 13), 14), we get

$$\Gamma(u+n) = u(u+1)\cdots(u+n-1)\Gamma(u); \tag{15}$$

and this gives

$$\Gamma(n) = 1 \cdot 2 \cdot 3 \cdots n - 1 = n - 1!,$$
 (16)

on replacing n by n-1 and u by 1.

A formula occasionally useful is

$$\frac{1}{a^n} = \frac{1}{\Gamma(u)} \int_0^{\infty} e^{-ax} x^{n-1} dx. \qquad (17)$$

It is obtained from 2) by replacing x, by ax.

5 The Γ function is continuous for any u>0 This follows from 669, 1 and 663, Ex 1

The derivative is given by

$$\Gamma'(u) = \int_{0}^{\infty} e^{-x} x^{u-1} \log x \, dx, \quad u > 0.$$
 (18)

This follows from 683, 2 Similarly

$$\Gamma^{11}(u) = \int_{-e}^{\infty} e^{-x}x^{u-1}\log^2 x \, dx, \quad u > 0.$$
 (19)

We can now get a good idea of the graph of \(\Gamma(u) \) In fact, the

expression 2) shows that $\Gamma(u) > 0$ for all u > 0From

From 13) we see that

$$\Gamma(u) = \int_{0}^{t} + \int_{0}^{u}$$

we see that

 $R \lim \Gamma(\alpha) = +\infty$

$$\lim \Gamma(u)\!=\!+\infty$$

From 19) we see that $\Gamma''(u) > 0$, and hence the graph of $\Gamma(u)$

is conçave Since $\Gamma(1) = \Gamma(2)$, the curve has a minimum between 1 and 2

Its value is 1 46163 6 We establish now the important relation connecting the B

> $B(u, v) = \frac{\Gamma(u)\Gamma(v)}{\Gamma(u+v)}$ (20

and I functions. From 17) we have

$$\frac{1}{(1+y)^{n+s}} = \frac{1}{\Gamma(n+y)} \int_{0}^{\infty} e^{-(1+y)x_{2}^{n+s-1}} dx$$

Hence by 1)

$$B(u,v) = \int_0^\infty \frac{y^{u-1}dy}{(1+y)^{u+v}} = \frac{1}{\Gamma(u+v)} \int_0^\infty dy \int_0^\infty x^{u+v-1} y^{u-1} e^{-(1+y)x} dx. \quad (21)$$

We may invert the order of integration, by 680, 3.

For, in the first place

$$f(xy) = \frac{x^{u+v-1}y^{u-1}}{e^{(1+y)x}}$$

is continuous in $R = (0\infty0\infty)$, except on the lines x = 0, y = 0.

Secondly,

$$\int_0^{\infty} f dx$$

is uniformly convergent in any (α, β) , $\alpha > 0$, by 663, Ex. 1.

Thirdly,

$$\int_0^\infty f dy$$

is uniformly convergent in any (a, b), a > 0.

Finally,

$$L = \int_0^\infty dx \int_0^\infty f dy$$

exists. For in

$$\Gamma = \int_0^\infty \frac{y^{u-1}dy}{e^{(1+y)x}},$$

set xy = t, x > 0. Then

$$Y = e^{-x} x^{-u} \int_0^{\infty} e^{-t} t^{u-1} dt$$

$$=e^{-x}x^{-u}\Gamma(u).$$

Hence for a > 0,

$$L_a = \int_a^{\infty} dx \int_0^{\infty} f dy = \Gamma(u) \int_a^{\infty} e^{-x} x^{r-1} dx.$$

But

$$\lim_{\alpha=0}\int_a^\infty e^{-x}x^{r-1}dx=\Gamma(v).$$

Hence

$$L = \lim_{\sigma \to 0} L_{\sigma} = \Gamma(u)\Gamma(v). \tag{22}$$

Thus all the conditions of 680, 3 being fulfilled, we have L=K. From 21), 22), we have 18).

CHAPTER XVI

MULTIPLE PROPER INTEGRALS

Notation

- 693 1 In Chapters MI and XIII the theory of proper integrals of functions of one variable was developed. We now take up the corresponding theory with reference to functions of several variables.
- 2 We begin by explaining a notation which we shall system stically employ in the following and which is similar to that used in the earlier chapters
- In the cannot conspict the same that the contract of the same temperature of

$$\widetilde{S}_{n} = \Sigma M d$$
 $S_{n} = \Sigma m d$

(1

It sometimes happens that we are considering points of two or more aggregates %, % Then we shall write

$$\bar{S}_{n_0}$$
 S_{n_0}

denote by F so that

where the subscript indicates that the auzzs 1) are taken over the aggregates H B respectively

3 We shall denote the maximum and minimum of f in \mathfrak{A} by M and m respectively The greater of |M| and |m| we shall

$$|f(x_1 \quad x_n)| \le F$$
 in \mathfrak{A} .

4. The oscillation of $f(x_1, \dots x_m)$ in the cell d_i is

 $\omega_{\scriptscriptstyle 1} = M_{\scriptscriptstyle 1} - m_{\scriptscriptstyle 1}$

The sum

$$\Omega_D f = \Sigma \omega_i d_i = \overline{S}_D - \underline{S}_D$$

is the oscillatory sum of f for the division D.

Upper and Lower Integrals

694. The sums \underline{S}_D , \overline{S}_D form a limited aggregate, D representing any division of norm $\leq d_0$; moreover

 $\underline{S}_D \leq \overline{S}_D$.

For

 $m \leq m_i \leq M_i \leq M$.

Hence

 $\sum md_i \leq \sum m_id_i \leq \sum Md_id_i \leq \sum Md_i$

or

$$m\Sigma d_{\iota} \leq \underline{S}_{D} \leq \overline{S}_{D} \leq M\Sigma d_{\iota}. \tag{1}$$

Since \mathfrak{A} is less than some fixed number, and the theorem follows at once from 1).

695. 1. Let $f(x_1, \dots x_m) \equiv 0$ in \mathfrak{A} . Let D and Δ be any two rectangular divisions of space. Let E be the division of space formed by superimposing the division Δ on D, or what is the same, the division D on Δ . Then

$$\bar{S}_{E} \leq \bar{S}_{D}, \quad \bar{S}_{E} \leq \bar{S}_{\Delta}.$$

For, let d_i be one of the cells of D which is subdivided, on superimposing Δ .

Let

$$d_{i1}, d_{i2}, \cdots$$

denote the cells of E in d, containing points of \mathfrak{A} . Then, to the term M_id_i in \overline{S}_D , corresponds the term

in \bar{S}_E . But $\begin{aligned} & \sum_{\kappa} M_{\iota\kappa} d_{\iota\kappa} \\ & M_{\iota\kappa} \leq M_{\iota}, & \sum_{\kappa} d_{\iota\kappa} \leq d_{\iota}. \end{aligned}$ Hence $\begin{aligned} & \sum_{\kappa} M_{\iota\kappa} d_{\iota\kappa} \leq \sum_{\kappa} M_{\iota} d_{\iota\kappa} \leq M_{\iota} d_{\iota}. \end{aligned}$

2 Similar reasoning shows that

If
$$f(x_1 x_m) \gtrsim 0$$
 in A,

$$S_{0} \subseteq S_{2}, \quad S_{\lambda} \subseteq S_{2}$$

696 1 Let $f(x_1 x_m) \ge 0$ be limited in the limited aggregate x.

 $S = \operatorname{Min} S_n$

with respect to all rectangular divisions D Then

$$\lim_{\Delta D} \delta_D = \delta \tag{1}$$

Let us imply the graphical representation of 231. The point of \Re lie in a cert in cube of d edge C. The representation of \Im is founded of m segments \Im , \Im , on the χ_1 , χ_2 tree. We shall supplie \Im taken so large that no coordinate of any point of \Im is at a distan. \Im \Im , \Im from the ends of these segments. This insures that the c(1) 1 of any D of norm \Im d₀ be within \Im , and therefore that \Im d 2C.

Since \bar{B} is the minimum of all \bar{B}_{D} , there exists for each $\epsilon > 0$ a division Δ , such that

$$\tilde{S} \le S_{\Delta} > \tilde{S} + \epsilon/2$$
 (2)

Let D be an arbitrary division Let us superimpose Δ on D, forming a division E

The division E is formed by interpolating certain points, let us any at most μ points in each of the segments G, G. The interpolation of one of these points may be interpreted as passing a plane parallel to one of the sides of G. Its effect is to subdivide certain of the cells of G. The volume of the cells of a Getter of the cells of G.

Hence the superimposition of Δ on D being equivalent to passing at most $m\mu$ planes parallel to the sides of \mathfrak{C} , affects cells of \mathfrak{C} belonging to the original division D, whose volume

$$V < m\mu dC^{n-1}$$
 (8)

Let Δ subdivide d_i , a cell of D containing points of \mathfrak{A} , into the cells d_i , d_i ...

containing points of A, and into the cells

$$\delta_{i1}, \delta_{i2} \cdots$$

containing no point of A.

Then

$$\overline{S}_D = \sum_i M_i d_i + R; \ \overline{S}_E = \sum_i M_{i\kappa} d_{i\kappa} + R,$$

where R denotes the sum of those terms common to \overline{S}_D and \overline{S}_{E^*} corresponding to cells of D unaffected by the division Δ .

But

$$d_{\iota} = \sum_{\iota \kappa} d_{\iota \kappa} + \sum_{\iota \kappa} \delta_{\iota \kappa}.$$

Hence

$$\overline{S}_D = \sum_{i,\kappa} M_i d_{i\kappa} + \sum_{i,\kappa} M_i \delta_{i\kappa} + R.$$

Therefore

$$\begin{split} 0 \leq & \overline{S}_{D} - \overline{S}_{E} = \Sigma (M_{\iota} - M_{\iota \kappa}) d_{\iota \kappa} + \Sigma M_{\iota} \delta_{\iota \kappa} \\ \leq & F \Sigma d_{\iota \kappa} + F \Sigma \delta_{\iota \kappa} = FV \\ < & m \mu dFC^{m-1}, \quad \text{by 3)}. \end{split}$$

If we take

$$d' < \frac{\epsilon}{2 \ m \mu F C^{m-1}},$$

we have

$$\overline{S}_D < \overline{S}_E + \epsilon/2$$
, for any $d \le d'$. (4)

But regarding E as formed by superimposing D on Δ ,

$$\overline{S}_{E} \leq \overline{S}_{\Delta}.$$
 (5

Hence 2), 4), 5) give

$$\overline{S} \le \overline{S}_D < \overline{S}_\Delta + \epsilon/2 < \overline{S} + \epsilon$$

or

$$0 < \overline{S}_{n} - \overline{S} < \epsilon$$

which proves 1).

2. A similar line of reasoning shows:

Let $f(x_1 \cdots x_m) \ge 0$ be limited in the limited aggregate \mathfrak{A} . Let

$$S = \text{Max } S_n$$

with respect to all rectangular divisions D. Then

$$\lim_{n\to\infty}\underline{S}_{D}=\underline{S}.$$

exist

697 Let f(x, x,) be limited in the limited aggregate & Then the limits

 $\lim \underline{S}_{\mu} = \lim \overline{S}_{\rho}$ exist and are finite

Let us take c > 0 so large that

$$g(x, x_-) = f(x_1 x_-) + c$$

is positive. Let M, N, be respectively the maxima of f and g in the cell d Obviously, N = M + c

We have seen in 696 1 that

Hence

hm ENd hm Ecd

$$\lim_{n \to \infty} \widetilde{S}_{\theta} = \lim_{n \to \infty} \Sigma M d = \lim_{n \to \infty} \Sigma (N - e) d$$

 $= \lim \Sigma Nd - \lim \Sigma \sigma d$ exists and is finite

To show that lim So

exists and is finite, we introduce the auxiliary function

$$h(x_i \quad x_m) = f(x_i \quad x_m) - c$$

and determine c> 0 so large that & is always negative in M

698 The limits S S whose existence was established in 697 are called the lower and upper integrals of f(x, x,) over the field a They are denoted respectively by

$$\underbrace{\int_{\mathbb{R}} f(x_1 \quad x_n) d\mathcal{H}}_{\mathbb{R}} = \underbrace{\int_{\mathbb{R}} f(x_1 \quad x_n) dx_1}_{\mathbb{R}} \quad dx_n,$$

$$\underbrace{\int_{\mathbb{R}} f(x_1 \quad x_n) d\mathcal{H}}_{\mathbb{R}} = \underbrace{\int_{\mathbb{R}} f(x_1 \quad x_n) dx_1}_{\mathbb{R}} \quad dx_n$$
(1)

When the lower and upper integrals 1) are equal, we denote their common value by

$$\int_{\mathbb{R}} f(x_1 - x_n) dX = \int_{\mathbb{R}} f(x_1 - x_n) dx_1 - dx_n, \qquad (2)$$

it is called the integral of f over the field \mathfrak{A} . In this case $f(x_1 \cdots x_m)$ is said to be integrable in \mathfrak{A} . We also say the integral 2) exists.

The integrals 1), 2) are called m-tuple or multiple integrals.

699. 1. Let $f(x_1 \cdots x_m)$ be limited and integrable in the limited field \mathfrak{A} . Let D be any rectangular division of norm d, and ξ , any point of \mathfrak{A} in the cell d. Then

$$\lim_{d\to 0} \Sigma f(\xi_i) d_i = \int_{\mathfrak{A}} f d\mathfrak{A}. \tag{1}$$

Conversely, if this limit exists, however the D's and E's be chosen, the upper and lower integrals of f are equal, and f is integrable.

For,
$$m_{\iota} \leq f(\xi_{\iota}) \leq M_{\iota}.$$
 Hence
$$\sum m_{\iota} d_{\iota} \leq \sum f(\xi_{\iota}) d_{\iota} \leq \sum M_{\iota} d_{\iota}.$$
 (2)
As
$$\lim \sum m_{\iota} d_{\iota} = \int_{\mathfrak{A}},$$

$$\lim \sum M_{\iota} d_{\iota} = \overline{\int_{\mathfrak{A}}}$$

are equal, we get 1) on passing to the limit d = 0 in 2).

The reader will observe that this reasoning is precisely similar to the first half of the demonstration in 493. The second half of our theorem is proved by a reasoning exactly similar to the second half of the demonstration of 493. Instead of the interval b-a, we have here a cube of volume C^m .

2. The theorem 1 shows us that we may take

$$\lim_{d=0} \sum f(\xi_{\kappa}) d_{\kappa}$$

when it exists as a second definition of the integral of f over A.

700. 1. The theorems of 495, 496, 497, and 498 may now be extended without trouble to functions of several variables. For convenience of reference we restate them here for this general case.

- 2 In order that the limited function f(z, z) be integrable in the limited field U, it is necessary and sufficient that the oscillatory sum $\Omega_A f = 0$ as the norms of the divisions D converge to 0
- 3 If the limited function f(x1 xm) is integrable over the limited field I it is integrible over any partial field of I
- 4 In order that the limited function f(x, x,) be integrable in the limited field & st is necessary and sufficient that for each e>0 there exists a division D for which the oscillatory sum

$\Omega f \in C$

5 In order that the limited function f(x, x,) be integrable in the limited field 4 it is necessary and sufficient that for each pair of postere numbers we of there exists a division D such that the sum of the cells of D in which the oscillation of f is > w, is < or

PTAMPLES

701. 1 Let % be the square (9) 9 1) Let

f(x, y) =0 for x or y irrational.

Then f is integrable by 00 5. For $f \approx > \frac{1}{d}$ only on the lines x = 1]]]] the depominators of the fractions being Eq. On each of these lines the oscillation in a 7 I tile interval is 5. On all other I are the oscillation Obviously there exists for each . a division for which the sum of the equares in which the oscillation is $\sum_{n=1}^{k}$ is $< \sigma$ and the integral is zero

2 Let I embrace the points x y of the square (0101) for which z is rational,

 $f(x, y) = \frac{1}{n}$ for $x = \frac{m}{n}$ on, a relative prime

Then f is integrable in M, as the above example shows.

Content of Point Aggregates

702 1 We extend now the notion of content etc., considered in 514 seq to limited aggregates in R. Let us effect a rectan g ilar division of space of norm & Let

$$d_1$$
, d_2 , d_3 ,

be those cells containing at least one point of the limited aggregate \mathfrak{A} ; while d!, d', d', ...

denote those cells, all of whose points lie in A.

Then the limits

$$\overline{\mathfrak{I}} = \lim_{\delta = 0} \Sigma d_{\kappa}, \qquad \underline{\mathfrak{I}} = \lim_{\delta = 0} \Sigma d_{\kappa}' \tag{1}$$

exist, and are finite.

For, let us introduce the auxiliary function $f(x_1 cdots x_m)$, whose value shall be 0 in \mathfrak{R}_m , except at the points of \mathfrak{U} , where its value is 1. Then, using the notation and results of the previous articles, we have:

$$\widetilde{\mathfrak{A}}_{D} = \sum M_{\kappa} d_{\kappa} = \sum d_{\kappa},$$

$$\underline{\mathfrak{A}}_{D} = \sum m_{\kappa} d_{\kappa} = \sum d_{\kappa}'.$$

$$\lim_{\Delta \to 0} \widetilde{\mathfrak{A}}_{D}, \quad \lim_{\Delta \to 0} \underline{\mathfrak{A}}_{D}$$

But by 697,

exist, and are finite.

2. The numbers $\widehat{\mathfrak{A}}$, $\underline{\mathfrak{A}}$ are called the upper and lower content of ${\mathfrak{A}}$ We have thus:

$$\overline{\mathfrak{A}} = \int f d\mathfrak{A}, \qquad \underline{\mathfrak{A}} = \int f d\mathfrak{A}.$$

When $\mathfrak{A} = \mathfrak{A}$, their common value is called the *content* of \mathfrak{A} . We denote it by

Cont \mathfrak{A} ,

or when no ambiguity arises, by I.

To be more explicit it is often convenient to set

$$\overline{\mathfrak{A}} = \operatorname{Cont} \mathfrak{A}, \qquad \mathfrak{A} = \operatorname{Cont} \mathfrak{A}.$$

A limited aggregate having content is measurable. Thus, when I is measurable.

Cont
$$\mathfrak{A} = \int_{\mathfrak{A}} f d\mathfrak{A}$$
.

The content of a measurable aggregate in \Re_2 is called its area; in \Re_3 the content is called *volume*. We shall also use the term *volume* in this sense, when n > 3.

wnte

8 As immediate consequence of the reasoning of 1, we have.
Let D be a partial aggregate of M Then

\$\<\vec{n}, \vec{n}<\vec{n}

703 By the aid of the auxiliary function employed in 702 we can state at once criteria in order that X is measurable

1 For A to be measurable, it is necessary and sufficient that the sum of the cells containing both points of A and points not in A converse to 0, as the norm of the division $\Rightarrow 0$

This follows from 700, 2

2 In order that N be measurable, it is necessary and sufficient that for each e>0, there exists a division such that the sum of the cells embracing both points of N and not of N is $<\epsilon$

This follows from 700, 4

Frontier Points

704 1 The frontier & of any aggregate U is complete.

For, let p be a limiting point of &

Then in any $D_{\epsilon}^{\bullet}(p)$, there are points of \mathfrak{F} — If ϵ is such a point, there are points not belonging to \mathfrak{F} in any $D_{\epsilon}^{\bullet}(\mathfrak{F})$ —We may take η so small that D_{ϵ} lies in D_{ϵ} —Hence p is a frontier point of \mathfrak{F}

2 Let % and 2 be two point aggregates Let

 $D = \text{Dist } (x, y) = \sqrt{(x_1 - y_1)^3 + \dots + (x_n - y_n)^3}$ be the distance between a point x of $\mathfrak A$ and a point y of $\mathfrak B$. Let δ be the minimum of D as x rous over $\mathfrak A$, and y runs over $\mathfrak B$. Then $\delta \supseteq 0$, and is finite. We say δ is the distance of $\mathfrak B$ from $\mathfrak B$, and

$$\delta = \text{Dist}(\mathfrak{A}, \mathfrak{B})$$

In certain cases, I way reduce to a single point a

3 If X B are limited and complete, there is a point a in A, and a point b in B, such that

If Dist (A, B) > 0, the two points a, b are frontier points

For, we may regard $x_1 \cdots x_m$, $y_1 \cdots y_m$ as the coördinates of a point z in a 2m-way space \mathfrak{R}_{2m} . We form an aggregate \mathfrak{C} whose points z are obtained by associating with each x of \mathfrak{A} , every y of \mathfrak{B} . Then the domain of definition of $\mathrm{Dist}(x,y)$ in 2, considered as a function of 2m variables, is precisely \mathfrak{C} . To represent \mathfrak{C} we may employ 2m axes, as in 231. Obviously \mathfrak{C} is limited and complete, since \mathfrak{A} and \mathfrak{B} are.

Then by 269, 2, there exists a point $(a_1 \cdots a_m, b_1 \cdots b_m)$ in \mathfrak{C} , at which D takes on its minimum value. Then

$$a = (a_1 \cdots a_m), \qquad b = (b_1 \cdots b_m)$$

are the points whose existence was to be proved.

The points a, b are frontier points of $\mathfrak A$ and $\mathfrak B$ respectively. For, if they were inner points, the distance between $D_{\delta}(a)$ and $D_{\delta}(b)$ equals

Dist $(a, b) - 2 \delta < \text{Dist } (a, b)$.

4. Let B be a partial aggregate of A. If the distance between the frontiers of A and B is not 0, we say B is an inner partial aggregate of A; also A is an outer aggregate of B.

Discrete Aggregates

705. 1. Definition. An aggregate of content 0 is discrete. Obviously, if $Cont \mathfrak{A} = 0$,

M is discrete.

2. Every limited point aggregate of the first species is discrete. Let \mathfrak{A} embrace at first, only a finite number of points, say n points. Let us effect a cubical division of space of norm

$$\delta < \sqrt[m]{\frac{\epsilon}{n}}$$

such that the points of $\mathfrak A$ lie within their respective cells. Then the sum of the cells containing the points $\mathfrak A$ is

$$\sum v_{\kappa} \leq n\delta^m < \epsilon$$
.

Thus $\mathfrak A$ is discrete, and the theorem is true for aggregates of order 0. Let us therefore assume the theorem is true for aggregates of order n-1 and show it is true for order n.

By 265, A (*) embraces only a finite number of points, say

We can, as just seen, inclose these within cells of total volume $\leq \epsilon/2$. The points of $\mathfrak A$ not in these cells form an aggregate $\mathfrak B$ of order n-1. By hypothesis we can effect a division of space, such that the total volume of the cells containing both points of $\mathfrak B$ and not of $\mathfrak B$ is $<\epsilon/2$. Thus the division formed by superimposing these two divisions is such that the volume of the cells containing both points of $\mathfrak B$ ind not of $\mathfrak B$ is $<\epsilon$.

706 Let I be a limited aggregate whose frontier points & form a

discrete aggregate. Then M is measurable

For using the notation of 702 the volume of those cells of a
discission D containing both points of M and not of M, is

$$\tilde{\mathfrak{A}}_{\rho} - \mathfrak{A}_{\mu} \leq \tilde{\mathfrak{A}}_{\rho}$$

where Fo is the volume of those cells containing at least a point of B But, as F is discrete,

$$\mathfrak{F}_o = 0$$

Hence, by 703, 1, M is measurable

707 1 Let \Re_n be an m way space. Let us give certain of the coordinates of $x = (x_1, x_n)$ fixed values. For example, let $x_{n+1} = t_{n+1}$, $x_n = a_n$. The aggregate of points $x = (x_1, x_n, a_{n+1})$.

 a_n) may be regarded as constituting a piral space, \Re , lying in \Re . The point x when considered as belonging to \Re , may be denoted more shortly by $x = (x_n - x_n)$

2 Let A be a limited aggregate lying in \Re_p . If we consider A as lying in an m way space \Re_m m>p, it is discrete

For , let \mathfrak{A} the m a cube C, of volume C in $\mathfrak{B}_{n,0}$ o large that none of the points of \mathfrak{A} come undefinitely near the arise of C. Then the upper content of \mathfrak{A} relative to \mathfrak{B}_{n} is C. We can effect a division D of \mathfrak{B}_{n} of norm d such that the points of \mathfrak{A} is within the cells of D. Then the volume of all the cells containing points of \mathfrak{A} is less than

Cd*** 2.

which converges to 0, with d

708. 1. Let $y = f(x_1, \dots x_m)$ be defined over an aggregate \mathfrak{A} . Let $x = (x_1, \dots x_m)$, $x' = (x_1 + h_1, \dots x_m + h_m)$ be two points of \mathfrak{A} . The increment that f receives when x passes to x' we have denoted by Δf . Let us set

$$\Delta x = \text{Dist}(x, x') = \sqrt{h_1^2 + \dots + h_m^2},$$

and call

 $\frac{\Delta f}{\Delta x}$

the total difference quotient of f. The point x' may or may not be restricted to remain near x; if so, it will be stated.

2. Let the limited functions

$$y_1 = f_1(x_1, \dots x_m), \dots y_n = f_n(x_1, \dots x_m), \quad n = m + p \ge m$$

have limited total difference quotients in the limited discrete aggregate A. Then B, the y-image of A, is also discrete.

For, let us effect a cubical division of the x-space of norm d. Since the difference quotients are limited in \mathfrak{A} , there exists a fixed G, such that $|\Delta f| < dG$, $\iota = 1, 2, \dots n$,

as x ranges over any one of the cells d_i of D. Hence each coördinate y_i remains in an interval of length < dG as x ranges over the points of $\mathfrak A$ in d_i . Therefore $y = (y_1, \dots y_n)$ remains within a cube of volume d^nG^n . Hence the points of $\mathfrak B$ have an upper content

$$< \widetilde{\mathfrak{Z}} d^n G^n = d^p G^n \widetilde{\mathfrak{Z}} d^m = d^p G^n \widetilde{\mathfrak{A}}_{D}.$$

As $\lim \widetilde{\mathfrak{A}}_D = 0$,

Cont $\mathfrak{B} = 0$.

3. As a corollary of 2 we have:

In the region R let

$$y_1 = f_1(x_1, \dots x_m), \dots y_n = f_n(x_1, \dots x_m) \qquad n \equiv m$$

have limited first partial derivatives.

Let $\mathfrak A$ be a limited inner discrete aggregate. Then $\mathfrak B$, the image of $\mathfrak A$, is discrete.

4 Let the limited functions

$$y_1 = f_1(x_1 \qquad x_n), \qquad y_n = f_n(x_1, \qquad x_n) \qquad n = m+p > m$$

have I mited total difference quotients in the limited agjregate A, except at points of a discrete aggregate Δ . In the cells of any cubical division of norm $d \leq d_0$ let at least m of these difference quotients remain limited. Then the unage B of A is discrete

For, consider one of the cells d containing a point of Δ . At least m of the coordinates of a point y remain in intervals of length

All we can say of the other coordinates of y is that they remain in intervals of length 2F where |f| < F, i = 1, 2, n. Thus the image of the points of $\mathfrak A$ in the cells d has an upper content

$$<\Sigma (Gd)^n(2F)^p = G^n 2^p F^p \Sigma d^n = 2^p F^p G^n \widetilde{\Delta}_p < \varepsilon/2,$$

ıf d₀ ıs taken small enough

The content of the image of the other cells d_x is

$$< \sum_{a} d^{a}G^{a} \le d^{p}G^{a}\mathfrak{A}_{D}$$

As $p \lessgtr 1$, we can take d_0 sufficiently small, so that the content of these cells is $<\epsilon/2$

709 An important class of discrete aggregates is connected with functions having limited variation, which we now define Cf 509 seq

Let $f(z_1 - z_n)$ be limited in the limited aggregate $\mathfrak A$. Let D be a cubical division of space of norm $d \leq d_0$. Let the oscillation of f in the cell d, be ω . If there exists a number $\tilde{\omega}$ such that

$$\sum \omega_n d^{m-1} \leq \tilde{\omega}_1$$
 (1)

however D is chosen, we say that $f(x_1 - x_m)$ has limited variation in $\mathfrak A$, otherwise it has unlimited variation

From 1) we have

$$\sum \omega_n \leq \frac{\tilde{\omega}}{J^{m-1}}$$
 (2)

710. Let the limited functions

$$y_1 = f_1(x_1 \cdots x_m) \cdots y_{n-1} = f_{n-1}(x_1 \cdots x_m)$$
 $n = m + p > m$

have limited total difference quotients in the limited aggregate A. Let $y_n = f_n(x_1 \cdots x_m)$

have limited variation in \mathfrak{A} . As $x=(x_1 \cdots x_m)$ ranges over \mathfrak{A} , let

 $y = (y_1 \cdots y_n)$ range over \mathfrak{B} . Then \mathfrak{B} is discrete.

For, let us effect a division of the x-space of norm d. Then $y_1, \dots y_{n-1}$ remain in intervals of length $\langle dG$ as x ranges over the points of $\mathfrak A$ in one of the cells d_{κ} . Thus if ω_{κ} is the oscillation of f_n in d_s , the point y remains in a cube of volume

$$< d^{n-1}G^{n-1}\omega_{\kappa}$$

when x ranges in d_{κ} . Thus the upper content of \mathfrak{B} is

$$< d^{n-1}G^{n-1}\Sigma\omega_{\kappa}$$

$$< d^p G^{n-1} \omega$$
, by 709, 2).

As this converges to 0 as $d \doteq 0$, \mathfrak{B} is discrete.

Properties of Content

- 711. 1. Let A be a limited aggregate. With the points of A let us form the partial aggregates A1, ... As, such that the aggregate of the common points, or of the common frontier points, of any two of these aggregates is discrete. We shall say that we have divided A into the unmixed aggregates A1, ... Also, A is the union of A, ... As.
- 2. Let the limited aggregate A be divided in the unmixed aggregates A., A., ... A. Then

$$\overline{\mathfrak{A}} = \overline{\mathfrak{A}}_1 + \dots + \overline{\mathfrak{A}}_s$$
; $\underline{\mathfrak{A}} = \underline{\mathfrak{A}}_1 + \dots + \underline{\mathfrak{A}}_s$.

For, let D be a rectangular division of norm δ . Let $\overline{\mathfrak{F}}_n$ be the volume of all those eells of D which contain points of more than one of the aggregates \mathfrak{A}_1 \mathfrak{A}_r . Let $\overline{\mathfrak{A}}_{r,D}$ be the volume of those cells containing points of \mathfrak{A} , $\iota = 1, 2, \dots s$. Then

$$\overline{\mathfrak{A}}_{D} \equiv \overline{\mathfrak{A}}_{1D} + \dots + \overline{\mathfrak{A}}_{s, D} \leq \overline{\mathfrak{A}}_{D} + s \overline{\mathfrak{F}}_{D}. \tag{1}$$

Now, by hypothesis,

$$\lim_{n \to \infty} \overline{\delta}_{\theta} = 0$$

Hence passing to the limit in 1) we get

The other half of the theorem is similarly proved

3 If the aggregate A can be divided into the measurable unmixed aggregates A₁ A₁ it is measurable and

This follows as corollary of 2

4 Let A. A. he limited aggregates whose frontiers are discrete. Let A be the union of these aggregates. Then A is measurable and

For we may divide $\mathfrak A$ into $\mathfrak A_1$ — $\mathfrak A$ and these latter aggregates are unmixed by hypothesis — The aggregates $\mathfrak A_1$ — $\mathfrak A$, are also measurable by 706

- 712 1 Connected with any limited complete aggregate I of upper content I > 0 is an aggregate I obtained from I by a precess of syling as follows
- Let D_1 D_2 be a set of rectangular divisions of space, each formed from the preceding by superimposing a rectangular division on it. Let the norms of these divisions converge to 0

The division D_1 effects a division of \mathfrak{A} into unmixed partial aggregates. Let \mathfrak{A}_1 denote those partial aggregates whose upper content is >0. Then by 711 2 $\mathfrak{A}_1=\mathfrak{A}$

Similarly the division D_s defines a partial aggregate of \mathfrak{A}_t and hence of \mathfrak{A} such that $\mathfrak{A}_s = \mathfrak{A}$ etc. Let us consider the cells of D_s which contain points of \mathfrak{A}_s . As $s = \infty$ these cells diminish in size, and in the limit define s set of points \mathfrak{B} . The upper content of the points of \mathfrak{A} in the diminish mass of \mathfrak{A} in the point of \mathfrak{A} is $\mathfrak{A} = \mathfrak{A}_s$. On Thus each point of \mathfrak{B} is a limiting point of \mathfrak{A} and hence a point of \mathfrak{A} . We shall prove, moreover, that \mathfrak{B} is perfectly and the provided \mathfrak{A} .

For, suppose b were an isolated point of \mathfrak{B} . Let C be a cube whose center is b and whose volume is small at pleasure. Let a be the points of \mathfrak{A} in C. Let us divide C into smaller cubes, say of volume $\frac{1}{n}\overline{a}$. The points of \mathfrak{A} in at least n of these new cells must have an upper content >0. Thus there are other points of \mathfrak{B} in C besides b. Hence \mathfrak{B} has no isolated points. To show that \mathfrak{B} is complete, let B be a limiting point of B; it is therefore a point of A. The upper content of the points of A in any domain of B is A will therefore lie in one of the cells of D_n , n=1, D, Hence it is a point of D.

Finally,
$$\overline{\mathfrak{A}} = \overline{\mathfrak{B}}.$$

For, any cell of D_n which contains a point of \mathfrak{V} contains a point of \mathfrak{V}_n , and conversely any cell which contains a point of \mathfrak{V}_n contains a point of \mathfrak{V}_n , or is at least adjacent to such a cell.

- 2. The aggregate B may be called the sifted aggregate of A.
- 713. 1. We shall find it useful to extend the terms cells, division of space into cells, etc., as follows:

Let us suppose the points of any aggregate \mathfrak{A} , which may be \mathfrak{R}_m itself, arranged in partial aggregates which we shall call *cells*, and which have the following properties:

- 1°. There are only a finite number of cells in a limited portion of space.
 - 2°. The frontier of each cell is discrete.
 - 3°. Each cell lies in a cube of side $\geq \delta$.
- 4°. Points common to two or more cells must lie on the frontier of these cells.

We shall call this a division of A of norm &.

2. Let Δ be such a division of space. Let $\mathfrak A$ be a limited aggregate. As in 702, $\overline{\mathfrak A}_{\Delta}$ may denote the content of all the cells of Δ which contain at least our point of $\mathfrak A$; while $\underline{\mathfrak A}_{\Delta}$ may denote the content of those cells *all* of whose points lie in $\mathfrak A$.

3 Let A be an aggregate formed of certain of these cells, A., Then I is measurable, and

This is a corollary of 711, 3

114 Let A be a limited point aggregate, and A a division of space of norm &, not necessarily a rectangular division Then

$$\lim_{n \to \infty} \widetilde{\mathcal{H}}_3 = \mathcal{H}, \quad \lim_{n \to \infty} \widetilde{\mathcal{H}}_3 = \underline{\mathcal{H}}$$
 (1)

Let us prove the first half of 1), the other half is similarly established

For each e>0 there exists a cubical division D of norm d such

that
$$\mathfrak{A} \leq \mathfrak{A}_{\mathfrak{p}} < \mathfrak{A} + \epsilon/2$$
. (2

Let D' be another cubical division of norm d'

Let By denote the volume of all those cubes containing points of Ha We can choose d so small that

$$\widetilde{\mathfrak{A}}_{\rho} \leq \widetilde{\mathfrak{B}}_{\rho} < \widetilde{\mathfrak{A}}_{\rho} + \epsilon/2$$

Then 2) gives 948>0€≥8

(3 Let A be any division of space, not necessarily cubical, of norm

8<1d Then \$\overline{\Pi}_2\$ contains every point of \$\overline{\Pi}_1\$, and is a part of \$\overline{\Pi}_2\$, since

the distance of M to Br is Zd" Hence, by 702, 3, and 713, 3.

91.<90.

This gives with 3) 91≤91,<91+€

for any 8≤1 d'

715 1 Let I be a himited aggregate If I is not complete, let us add to it its lacking limiting points. The resulting aggregate 91 may be calle I the completed a paregate of I

A limited aggregate A, and its completed aggregate B, have the same upper content

For, let us effect a rectangular division D of norm d. The cells containing points of \mathfrak{B} fall in two classes: 1°, those cells d_1, d_2, \cdots containing points of \mathfrak{A} ; 2°, those cells e_1, e_2, \cdots containing no point of \mathfrak{A} . Each of these latter cells, as e_i , is contiguous to at least one cell d_{κ} . If e_i , \cdots are contiguous to d_{κ} , we will join them to d_{κ} , to form a new cell δ_{κ} , in such a way that each e-cell has been joined to some one d-cell.

The cells δ_1 , δ_2 , ... together with the cells d_1 , d_2 , ... which remain unchanged by this process of consolidation, define a division Δ of the kind considered in 713. The norm δ of this division is evanescent with d.

Now, for the division Δ ,

$$\overline{\mathfrak{A}}_{\Delta} = \overline{\mathfrak{B}}_{\Delta}.$$

By 714, the left side $\doteq \overline{\mathfrak{A}}$. Hence

$$\mathfrak{B}=\overline{\mathfrak{A}}.$$

2. The lower contents \(\mathbb{I}, \mathbb{B} \) do not need to be equal.

For example, let $\mathfrak{A} = \text{rational points in the interval } \mathcal{J} = (0, 1)$. Then $\mathfrak{B} = \mathcal{J}$.

But

$$\underline{\mathfrak{A}}=0, \qquad \underline{\mathfrak{B}}=1.$$

3. Let A be measurable. Then A, and its completed aggregate B. have the same content.

For, we have just seen that

$$\mathfrak{A} = \overline{\mathfrak{A}} = \overline{\mathfrak{B}}.\tag{1}$$

On the other hand, every inner point of A is an inner point of B. Hence

 $\mathfrak{A}_{D} \leq \mathfrak{B}_{D}$.

Hence, passing to the limit,

$$\mathfrak{A} = \underline{\mathfrak{A}} \leq \underline{\mathfrak{B}} \leq \overline{\mathfrak{B}}.$$
 (2)

Hence 1), 2) give

$$\mathfrak{A}=\mathfrak{B}=\overline{\mathfrak{B}}.$$

4 If A is measurable, the content of A and its derivative A' are equal

For, let B be the completed aggregate of M. Since every inner point of M is an inner point of M', and every point of M' is in B we have for any cubical division D, of norm d,

 $\mathfrak{A}_{\rho} \leq \mathfrak{A}_{\rho}' \leq \mathfrak{A}_{\rho}' \leq \mathfrak{B}_{\rho}$ Passing to the limit d=0, this gives, since \mathfrak{A} is measurable,

But, by 3, A = B Hence 3) gives

$$\mathfrak{A}=\widehat{\mathcal{A}}_{\iota}=\mathfrak{A}_{\iota}$$

716 Let A be a limited aggregate whose upper content is A. Let B be a partial aggregate depending on u such that

Let D be a restangular division of norm d Then for each e>0 there exists a pair of numbers up do such that

$$\tilde{X}_0 - \tilde{\mathfrak{D}}_{\bullet,0} < \epsilon$$
 (1

for any $0 < u \le u_0$ $0 < d \le d_0$

For, if $d \le d_0$, $\widetilde{A} \le \widetilde{A}_p < \widetilde{A} + \epsilon/2$,

and, if $u \le u_0$, $\overline{X} = \epsilon/2 < \overline{\mathfrak{D}}$.

But Hand

U_{n,0}≤π₀

Thus $\mathfrak{A} = \epsilon/2 < \mathfrak{B}_{\bullet} \leq \mathfrak{B}_{\bullet} = \mathfrak{A}_{\mathfrak{p}} < \mathfrak{A} + \epsilon/2,$

which establishes 1)

Plane and Rectifinear Sections of an Aggregate

717 1 Let \mathfrak{A} be an aggregate in \mathfrak{R}_n As $x = (x_1 \ x_n)$ ranges over \mathfrak{A} x_i will range over an aggregate x_i on the x_i axis, which we call the projection of \mathfrak{A} on this axis

The points of \mathfrak{N}_m for which one of the coördinates as x_i has a fixed value $x_i = \xi_i$, lie in an m-1 way plane, which we shall say is perpendicular to the x_i -axis. We may denote it by P_{ξ_i} or more shortly, by P_i . The points of \mathfrak{A} in P_i form a plane section of \mathfrak{A} corresponding to the point ξ_i in ξ_i , which we denote by \mathfrak{P}_{ξ_i} or \mathfrak{P}_i . We also say \mathfrak{P}_i is a plane section of \mathfrak{A} perpendicular to the x_i -axis.

- 2. As $x = (x_1 \cdots x_m)$ ranges over the points of \mathfrak{A} , the point $(x_1, \dots, x_{i-1}, 0, x_{i+1}, \dots, x_m)$ ranges over an aggregate \mathfrak{X} , in the plane $x_i = 0$, which may be called the m-1 way plane Π_i of the axes perpendicular to x_i . We call \mathfrak{X}_i , the projection of \mathfrak{A} on Π_i .
- 3. Let us fix all the coördinates of $x = (x_1 \cdots x_m)$, except x_i . Then x describes a right line parallel to the x_i -axis. Let a_i denote the points of $\mathfrak A$ on one of these lines. We shall call it a rectilinear section of $\mathfrak A$, parallel to the x_i -axis.
- 4. Let $\mathfrak A$ be limited and complete. Then the $\mathfrak P_i$ and the $\mathfrak a_i$, also the $\mathfrak X_i$ are complete.

Let us show that the \mathfrak{P}_i are complete. Let p be a limiting point in one of the \mathfrak{P}_i . Let $p_1, p_2 \dots$ (1

be a sequence of points in this plane which $\doteq p$. Then 1) is a sequence in \mathfrak{A} , and as \mathfrak{A} is complete, p lies in \mathfrak{A} , and hence in \mathfrak{P}_i .

Let us show that x_i is complete. In fact, let q be one of its limiting points. Let $q_1, q_2 \cdots$ be a sequence in x_i which = q. In each plane section \mathfrak{P}_{q_i} , take a point r_{κ} .

This gives a sequence $r_1, r_2 \dots$

whose limiting points lie in \mathfrak{A} , since \mathfrak{A} is complete. Moreover, the projection of these limiting points is q.

718. 1. Let A be a measurable aggregate.

Let ξ_{σ} denote those points of ξ_{τ} , for which the upper content of the frontier points of \mathfrak{P}_{τ} is \mathbb{F}_{σ} . Then ξ_{σ} is discrete.

For, let us effect a cubical division D of \mathfrak{R}_m of norm d. This effects also a division of norm d of the x_i -axis. Let $d_1, d_2 \cdots$ denote those intervals on this axis, embracing at least one point for which the frontier points of the corresponding plane section have upper

content \$\int \sigma \text{ If \$\vec{g}_0\$ denote the volume of those cells containing frontier points \$\vec{g}\$ of \$\vec{g}\$, we have

vo SoΣd, for any D

Let d=0 As \mathfrak{A} is measurable,

σ Cont r. ≃ 0

As σ>0. Contr.=0

2 In a similar manner we prove

Let X, denote those points of the projection of the measurable aggregate U on the plane 2 = 0 for which the content of the frontier points on the corresponding rectainear sections is 5 \u03c4 Then X, is discrete

8 Let χ be the projection of the measurable aggregate A on the x are Let D be a discusion of $\Re_n \partial$ form d Let f_1 f_2 denote those intervals on the x are containing frontier points of χ Let $\chi > 0$ $\sigma > 0$ be taken small at pleasure. If f_1 f_2 denote those f intervals containing points of χ for which the upper content of the corresponding plane sections g is $g \sim \chi$ exceed take g, so small that

$$\Sigma f' < \sigma$$
, $d < d$

For in the contrary case, the upper content $\bar{\mathfrak{h}}$ of the frontier points of \mathfrak{A} is $\mathbb{S}_{\gamma\sigma}$ (1

But % being measurable, & = 0, which contradicts 1)

Classes of Integrable Functions

719 1 Let $f(x_1 - x_n)$ be continuous at the limiting points of the limited complete field X. Then f is integrable in X.

For reasoning similar to that of 352 shows that we can effect a cubical division D, such that the oscillation of f in each cell of D containing points of $\mathfrak A$ is <<

2 In the limited complete aggregate A let the limited function $f(x_1 - x_n)$ be continuous, except at the points of a discrete aggregate B. Then f is integrable in A.

Since B is discrete, there exists a cubical division D such that the volume of those cells containing points of B is < c

Let \mathfrak{C}_D denote those cells which contain points of \mathfrak{A} , but do not contain points of \mathfrak{B} . Since f is continuous in \mathfrak{C}_D , we can effect a cubical division D' of \mathfrak{C}_D , such that the oscillation of f in any cell of D' is $< \omega$.

Then by 700, 4, f is integrable in \mathfrak{A} .

3. Let $f(x_1 \cdots x_m)$ have limited variation in the limited field \mathfrak{A} . Then f is integrable in \mathfrak{A} .

For.

$$\Omega_{D}f = \Sigma \omega_{\kappa} d_{\kappa} \leq d^{m} \Sigma \omega_{\kappa},$$

$$\leq d\tilde{\omega}$$
, by 709, 2).

Hence

$$\lim \Omega_D f = 0,$$

and f is integrable, by 700, 2.

- 720. As in 504, 505, 507, and 508, we may establish the following theorems:
- 1. Let $f(x_1 \cdots x_m)$ be a limited integrable function in the limited field \mathfrak{A} . Then $|f(x_1 \cdots x_m)|$ is integrable in \mathfrak{A} . [507.]
- 2. Let $f_1, f_2, \dots f_r$ be limited integrable functions in the limited field \mathfrak{A} . If $c_1, c_2, \dots c_r$ denote constants, then

$$c_1f_1+c_2f_2+\cdots+c_rf_r \qquad and \qquad f_1\cdot f_2\cdots f_r$$

are integrable in A. [504, 505.]

3. The converse of 1 is not necessarily true. For example, in a rectangle R let f(xy) = 1, for x, y rational;

=-1, for other points in R.

Obviously f is not integrable in R.

On the other hand, |f| obviously is integrable.

4. The product $f \cdot g$ may be integrable without either f or g being integrable in \mathfrak{A} . For example, in a rectangle R let f(xy) be defined as in 3; while

g(xy) = -1, for x, y rational;

=1, for other points of R.

Then fg = -1 in R, and is hence integrable in R.

721 Let $f(x_1 \quad x_m)$ be integrable in the limited complete field X. Let C be the points of X at which f is continuous. Then $\overline{C} = X$

For if A is discrete, the theorem is true, even if f has no points of continuity in A Let us therefore suppose A>0 Let B be the partial aggregate formed from A by the process of sitting, considered in 712

Let D be a rectangular division, and d one of its cells containing points of \mathfrak{D} , we can choose D so that no cell has points of \mathfrak{D} on its sides. Let a be the points of \mathfrak{T} in d. Since a is a partial aggregate of \mathfrak{T} $f(x_1-x_n)$ is integrable in a. The reasoning of 508 shows now that f must be continuous at one point, at least, of a and hence at an infinity of points of a.

Among these points, he points of B Thus every cell of the division D which contains a point of B contains a point of C

Hence

 $\vec{\Sigma} = \vec{\mathfrak{D}}$

Generalized Definition of Multiple Integrals

722 Let $f(x_1-x_n)$ be limited in the limited field $\mathbb N$ Let Δ be any division of space of norm δ into cells δ_1 , δ_2 , not necessarily rectangular Let $\mathbb N$, $\mathbb N$, be respectively the maximum and minimum of f in δ . Then

$$\lim_{\delta n} \tilde{S}_n = \lim_{\delta n} \Sigma \mathfrak{M}_{\delta} \delta = \int_{\mathbb{R}^d} d\mathfrak{M}$$

$$\lim S_a = \lim \operatorname{Ent} \delta = \iint d\mathfrak{A} \qquad (2)$$

Let D be a cubical division of norm d. Let d_v , d_x , be the cells of D containing points of $\mathfrak A$. We may denote their volumes by the same letters. Let $M_x = \operatorname{Max} f_i$ in d_i , also $F \subseteq \operatorname{Max} [f]$ in $\mathbb A$ and $g \subseteq 1$. Then for each e > 0, there exists a d such that

$$\left|\vec{S}_{B} - \int_{\mathbb{R}} \left| < \frac{\epsilon}{2} \right|$$
 (3)

where, as usual,

$$S_p = \Sigma M d_{\downarrow}$$

Furthermore we may choose d so small that

$$\overline{\mathfrak{A}}_{\mathcal{D}} - \overline{\mathfrak{A}} < \frac{\epsilon}{8 \, F}, \tag{4}$$

where

$$\overline{\mathfrak{A}}_D = \Sigma d_{\iota}$$
.

Consider now the division Δ . Those of its cells containing points of $\mathfrak A$ fall into two classes: 1°, those lying in only one cell of D; 2°, those lying in two or more cells of D. Let δ_{i1} , δ_{i2} , ... be the cells of the 1° class lying in d_i . Let δ_i , δ_i , ... be all the cells of the 2° class. Then the content of all the cells of Δ containing points of $\mathfrak A$ is

$$\Sigma \delta_{i\kappa} + \Sigma \delta_i' = \overline{\mathfrak{A}}_{\Delta}.$$

But since the frontier of $\overline{\mathfrak{A}}_D$ is discrete, there exists a δ_0 such that

 $\Sigma \delta'_{\iota} < \frac{\epsilon}{16 F'}, \qquad \delta \le \delta_0.$ (5)

As moreover $\overline{\mathfrak{A}}_{\Delta} \doteq \overline{\mathfrak{A}}$, by 714, we may suppose that

$$\overline{\mathfrak{A}}_{\Delta} - \overline{\mathfrak{A}} < \frac{\epsilon}{16 F}, \qquad \delta \leq \delta_0.$$
 (6)

From 5), 6) we have

$$|\Sigma \delta_{i\epsilon} - \overline{\mathfrak{A}}| < \frac{\epsilon}{8 F}$$

This with 4) gives finally

$$|\Sigma \delta_{is} - \widetilde{\mathfrak{A}}_{D}| < \frac{\epsilon}{4 E}$$
 (7)

Now

$$\overline{S}_{\Delta} = \Sigma \mathfrak{M}_{i\kappa} \delta_{i\kappa} + \Sigma \mathfrak{M}_{i}' \delta_{i}',$$

where \mathfrak{M}_{is} , \mathfrak{M}'_i are the maxima of f in δ_{is} , δ'_i respectively. Hence

$$\overline{S}_{\Delta} \equiv \Sigma M_{\epsilon} \delta_{\epsilon \kappa} + F \Sigma \delta_{\epsilon}', \tag{8}$$

wince

$$\mathfrak{M}_{\alpha} \gtrsim M_{\alpha}, \quad \mathfrak{M}'_{\alpha} < F.$$

Thus 5), 8) give

$$\bar{S}_{\Delta} < \Sigma M_i \delta_{i\alpha} + \frac{\epsilon}{4}$$
 (9)

Now

$$|S_D - \Sigma M \delta_{\omega}| = |\Sigma M (d_s - \Sigma \delta_{\omega})|$$

$$\leq F|\Sigma d_{i} - \Sigma \delta_{ii}| = F|\widetilde{\mathfrak{A}}_{i} - \Sigma \delta_{ii}|$$

$$<\frac{\epsilon}{7}$$
, by 7). (10

Thus 9), 10) give

$$\bar{S}_{a} < \bar{S}_{a} + \frac{\epsilon}{2}$$

(11

In the same way we may show that for a properly chosen cubical division E. $\bar{S}_z < S_s + \frac{e}{5}$ (12

From 3), 11), 12) we have

$$\left| \bar{S}_{a} - \bar{\int}_{\mathbf{H}} \right| < \epsilon, \qquad \delta \le \delta_{0}$$

This proves 1) In a similar manner we may demonstrate 2)

723 Let f(x, x,) be limited in the measurable field & Let A be an unmixed director of A of norm &, ento the cells &, &. As usual let

$$\underline{S}_{\lambda} = \sum m_i \delta_{\alpha}, \quad S_{\lambda} = \sum M \delta_{\alpha}$$

Let m be the maximum of S_{*} and M the minimum of \bar{S}_{*} for all divisions $\Delta, \delta = 0$ Then

$$m = \int_{\mathbb{R}} f dN$$
 $\mathfrak{M} = \int_{\mathbb{R}} f dN$

Let us divide one of the cells as & into two unmixed cells &. δ" This gives a new division Δ' Then the term m, δ in S., is replaced by the two terms

in S. Hence

$$m_1^*g_1^*+m_1^{**}g_1^{**}\geq m_1^*g_2^{**}$$

$$\underline{S}_{\lambda} \leq \underline{S}_{\lambda}$$

 $\underline{S}_{\lambda} < \underline{S}_{\lambda}$

Similarly

The theorem follows now from 722. For, there exists a division Δ , such that

 $\mathfrak{m} - \epsilon < \underline{S}_{\Lambda} \leq \mathfrak{m}. \tag{1}$

Let us now take a sequence of divisions Δ' , Δ'' , ... whose norms $\doteq 0$; each $\Delta^{(n)}$ being formed by subdividing the cells of $\Delta^{(n-1)}$. Then

 $\underline{S}_{\Delta} \equiv \underline{S}_{\Delta'} \equiv \underline{S}_{\Delta''} \cdots \doteq \int_{\mathfrak{A}} f d\mathfrak{A}. \tag{2}$

From 1), 2), we have

 $\left|\int_{\mathfrak{A}} f d\mathfrak{A} - \mathfrak{m}\right| < \epsilon;$

hence

 $\mathfrak{m} = \int_{\mathfrak{A}} f d\mathfrak{A},$ etc.

Properties of Integrals

724. Let $f(x_1 \cdots x_m)$ be limited and integrable in the limited field \mathfrak{A} . Let \mathfrak{B} be a partial aggregate depending on u, such that $\overline{\mathfrak{B}} \doteq \overline{\mathfrak{A}}$, as $u \doteq 0$. Then

 $\lim_{t \to 0} \int_{\mathfrak{B}} f d\mathfrak{B} = \int_{\mathfrak{A}} f d\mathfrak{A}. \tag{1}$

Since f is integrable over \mathfrak{A} ,

$$\Omega_D f < \epsilon/2$$
 (2)

for any division D of norm $d \leq d_0$, by 700, 2.

Moreover, by 716, if d_0 and u_0 are taken small enough,

$$\overline{\mathfrak{A}}_{D} - \overline{\mathfrak{B}}_{u,D} < \epsilon/2 F,$$
 (3)

where |f| < F in \mathfrak{A} .

Let d_1 , d_2 , ... be the cells of D containing points of \mathfrak{B}_u , and d'_1 , d'_2 , ... the cells containing only points of \mathfrak{A} . Then

$$\overline{S}_{\mathfrak{A}_{D}} = \sum M_{i} d_{i} + \sum M'_{i} d'_{i},$$

$$\overline{S}_{\mathfrak{B}_{u,D}} = \sum N_{i} d_{i},$$

where $N_i = \text{Max } f$ for points of \mathfrak{B} in d_i .

Hence

$$|\overline{S}_{\mathfrak{A}_{D}} - \overline{S}_{\mathfrak{B}_{u,D}}| \leq \Sigma (M_{\iota} - N_{\iota}) d_{\iota} + F \Sigma d_{\iota}'$$

$$< \epsilon, \quad \text{by 2), 3).}$$
(4

Let now d = 0 Then 4) gives

Hence

$$\left|\int_{u}-\int_{u}\right|\leq\epsilon$$

which gives 1)

725 1 Let f(x, xm) be limited in the measurable field & Let B be an outer field of A Let g(x, x,) = 0 in B except of the points of A where it = f(x, x_) Then

$$\int_{\mathbb{R}} f d\mathbb{X} = \int_{\mathbb{R}} g d\mathfrak{B} \quad \int_{\mathbb{R}} f d\mathbb{X} = \int_{\mathbb{R}} g d\mathfrak{B}$$

For, let D be a division of space of norm d not necessarily rectangular Let the uner cells of A be d_1 d_2 while d_1' d_1' denote cells containing frontier points of I i et W N denote the maxima of f g in d while M' N' are the maxima of f gin d. Then $S_n = \sum V d + \sum V d$

$$D_{p} = 2 \cdot 4 \cdot 4 \cdot 2 \cdot 4 \cdot 4$$

$$T_{n} = 2 \cdot \lambda \cdot d + 2 \cdot \lambda \cdot d'$$

Hence since $M = \lambda$ we have setting $f \le F$ in \mathfrak{A} ,

$$|\overline{S}_{D} - \overline{T}_{D}| \le F \Sigma d$$

Let now d=0 Since A is measurable we have the first part of our theorem The second part foll we likewise

2 In a similar manner we establish the following theorems

Let $f(x_1 x_m)$ be limited in the measurable field A Let $g(x_1 x_m) = f$ at inner joints of \mathcal{X} and = 0 at frontier points Then

f at inner 10 nts of A and = 0 at frontier points
$$\int_{-\infty}^{\infty} g dX = \int_{-\infty}^{\infty} f dX \qquad \int_{-\infty}^{\infty} g dX = \int_{-\infty}^{\infty} f dX$$

3 Let f(x1 xm, g(x1 xm) be limited in the measurable field M Let them be equal exe pt at the points of a discrete aggregate Then

SfdN = SgdN SdN = Sg M

726. 1. Let $f(x_1 \cdots x_m)$ be limited and integrable in the limited field \mathfrak{A} . Let \mathfrak{B} be a partial aggregate of \mathfrak{A} , such that $\overline{\mathfrak{A}} = \overline{\mathfrak{B}}$. Then

$$\int_{\mathfrak{A}} f d\mathfrak{A} = \int_{\mathfrak{B}} f d\mathfrak{B}. \tag{1}$$

Let D be a cubical division of space of norm δ . Let d'_i denote those cells containing points of \mathfrak{B} , and d''_i denote the cells containing points of \mathfrak{A} , but not of \mathfrak{B} . Then employing the usual notation,

 $\Sigma f(\xi_{\iota})d_{\iota} = \Sigma f(\xi_{\iota}')d_{\iota}' + \Sigma f(\xi_{\iota}'')d_{\iota}''.$

Since $\Sigma d'' \doteq 0$ as $\delta \doteq 0$, we have 1) on passing to the limit.

2. Let $f(x_1 \cdots x_m)$ be limited and integrable in the limited complete field \mathfrak{A} . Let \mathfrak{C} denote the points of \mathfrak{A} at which f is continuous. Then

$$\int_{\mathfrak{A}} f d\mathfrak{A} = \int_{\mathfrak{C}} f d\mathfrak{C}.$$

This follows from 1 and 721.

727. Let $f(x_1 \cdots x_m)$ be limited in the limited field \mathfrak{A} . If for any cubical divisions D, of norm $d \leq d_0$,

$$A < \Sigma f(x_i)d_i < B$$
;

then

$$A \leq \int_{\mathfrak{A}} f d\mathfrak{A} \leq \overline{\int_{\mathfrak{A}}} f d\mathfrak{A} \leq B. \tag{1}$$

For, in each cell d_i there are points x'_i , x''_i , such that

$$f(x'_i) < m_i + \sigma, \quad f(x''_i) > M_i - \sigma,$$

however small $\sigma > 0$ is chosen.

Hence

$$A \leq \sum f(x'_{i})d_{i} < \underline{S}_{D} + \sigma \sum d_{i}; \quad B = \sum f(x''_{i})d_{i} > \overline{S}_{D} - \sigma \sum d_{i}.$$
 (2)

Let

$$\sigma < \frac{\epsilon}{Cout.90}$$

Then passing to the limit d=0 in 2), we get

$$A - \epsilon \leq \underline{\int}_{\underline{n}} \leq \overline{\int}_{\underline{n}} \leq B + \epsilon.$$

From this we conclude 1) at once

728 Let f(x, x,) be limited in the limited field A Let A be divided into the unmixed fields II. II. Then

$$\begin{split} & \int_{\mathbb{R}} f d\mathbb{H} = \int_{\mathbb{R}_1} f d\mathbb{H}_1 + & + \int_{\mathbb{R}_2} f d\mathbb{H}_2, \\ & \int_{\mathbb{R}} f d\mathbb{H} = \int_{\mathbb{R}_1} f d\mathbb{H}_1 + & + \int_{\mathbb{R}_2} f d\mathbb{H}_2, \end{split}$$

For, let |f| < F in \mathfrak{A} Let D be a rectangular division of norm d As in 711, 2, let Mi a. M. a be the cells containing points of M. M. respectively, while To constitute the cells contuning points of more than one of the fields %,

$$|\bar{S}_p - (\bar{S}_{1,p} + + S_{1,p})| \le \varepsilon F \bar{\mathfrak{F}}_2$$

Letting d=0 in this relation, we get the first part of the theorem The rest is proved likewise

729 As in 504, 489, 4, 526, 2, 531, we may prove the following theorems

1 Let f1, f, be integrable in the limited field A Let c1, c, be constants and F=c,f,++c,f

Then

$$\int_{a} F dX = c_{i} \int_{a} f_{i} dX + + c_{i} \int_{a} f_{i} dX \qquad [504]$$

 Let f(x₁ x_m) be integrable in the limited field A and numer $ucally \le M$ Then | fdH | M Cont H

T489, 47

3 Let f(x1 xm), g(x1 xm) be integrable in the limited field U and let $f \le g$ Then $\int f dX < \int g dX$ F526 27

4. Let $f(x_1 \cdots x_m)$, $g(x_1 \cdots x_m)$ be integrable in the limited field \mathfrak{A} . Let $f \subseteq 0$; $\Theta = \text{Mean } g$, in \mathfrak{A} .

Then

$$\int_{\mathfrak{A}} fg d\mathfrak{A} = \Theta \int_{\mathfrak{A}} f d\mathfrak{A}.$$
 [531]

5. The following theorems are readily proved:

Let $f(x_1 \cdots x_m)$ be limited in the limited field \mathfrak{A} . If $f(x_1 \cdots x_m) > \lambda$ in \mathfrak{A} ,

 $\int_{\mathfrak{N}} f d\mathfrak{N} \geqslant \lambda \overline{\mathfrak{N}}.$

6. Let $f(x_1 \cdots x_m)$ be limited in the limited field \mathfrak{A} , and ≤ 0 . If \mathfrak{D} is a partial field of \mathfrak{A} ,

$$\overline{\int}_{\mathfrak{A}} f d\mathfrak{A} \, \overline{\geqslant} \, \overline{\int}_{\mathfrak{B}} f d\mathfrak{B}.$$

For,

$$\overline{S}_{\mathfrak{V}_{\boldsymbol{\mathcal{D}}}} \overline{\mathbb{S}}_{\mathfrak{V}_{\boldsymbol{\mathcal{D}}}}.$$

7. Let $f_1, \dots f_n$ be limited in the limited field \mathfrak{A} . Then

$$\begin{split} & \overline{\int}_{\mathfrak{A}} (f_1 + \dots + f_n) d\mathfrak{A} \leq \overline{\int}_{\mathfrak{A}} f_1 d\mathfrak{A} + \dots + \overline{\int}_{\mathfrak{A}} f_n d\mathfrak{A}, \\ & \int_{\mathfrak{A}} (f_1 + \dots + f_n) d\mathfrak{A} \geq \int_{\mathfrak{A}} f_1 d\mathfrak{A} + \dots + \int_{\mathfrak{A}} f_n d\mathfrak{A}. \end{split}$$

For, in any cell d_i of the division D_i

$$\max(f_1 + \dots + f_n) \leq \max f_1 + \dots + \max f_n,$$

$$\min(f_1 + \dots + f_n) \equiv \min f_1 + \dots + \min f_n.$$

8. Let f, g be limited in the limited field A. Then

$$\overline{\int}_{\mathfrak{A}} (f-g) d\mathfrak{A} \equiv \overline{\int}_{\mathfrak{A}} f d\mathfrak{A} - \overline{\int}_{\mathfrak{A}} g d\mathfrak{A},$$

$$\underline{\int}_{\mathfrak{A}} (f-g) d\mathfrak{A} \equiv \int_{\mathfrak{A}} f d\mathfrak{A} - \int_{\mathfrak{A}} g d\mathfrak{A}.$$

536 For, in any cell d, of the division D,

$$\operatorname{Max}(f-g) \leq \operatorname{Max} f - \operatorname{Max} g$$

Min(f-g) < Min f - Min g

9 Let f, g be limited in the limited field A and let f≤g

$$\int_{\mathbb{R}} f d\mathbb{R} \le \int_{\mathbb{R}} a d\mathbb{R} \quad \int_{\mathbb{R}} f d\mathbb{R} \le \int_{\mathbb{R}} f d\mathbb{R}$$

730 Let f(x1 Im) be limited in the limited field A Let A. denote the points of I at which if so If He is discrete for any o > 0,

$$\int_{\mathbb{R}} f t dt = \int_{\mathbb{R}} f t dt = 0$$

For, let

Hence

$$\sigma < \epsilon/4$$
 $|f| < F$

I et D be a division of norm δ Let d' denote the cells in which $|f| \ge \sigma$, while d' denotes the cells in which $|f| < \sigma$ Then

$$J_{\theta} = \sum f(\xi_{\alpha}) d_{\alpha} = \sum f(\xi'_{\alpha}) d'_{\alpha} + \sum f(\xi''_{\alpha}) d''_{\alpha}$$

$$|J_t| < F \Sigma d_* + \sigma \Sigma d_*^t$$

Let &= 0 The right side is

which establishes the theorem, by 727

731 Let f(x, x,) 50, be limited and integrable in the limited field I If

 $\int f dX = 0,$

the points A_{σ} , at which $f(x) \ge \sigma$, an arbitrarily small positive number, form a discrete aggregate Let 3 denote the points at which f = 0 If I to complete, 3 = 9

For

$$0 = \int_{\mathbf{q}} \ge \int_{\mathbf{q}} ,$$
 by 729, 6.

$$\overline{\int}_{\mathfrak{A}_{\sigma}} \overline{\geq} \sigma \overline{\mathfrak{A}}_{\sigma}$$
, by 729, 5.

Hence

$$\sigma \widetilde{\mathfrak{A}}_{\sigma} = 0.$$

Since $\sigma > 0$,

$$\mathfrak{A}_{\sigma}$$
 must = 0.

To prove the second part of the theorem, let b be a point of \mathfrak{B} , the sifted aggregate of \mathfrak{A} , at which f is continuous. Cf. 712.

Then if f>0, we can choose $\delta>0$ so small that $f\geq\lambda>0$ in $V_{\delta}(b)$. But the upper content of the points a of \mathfrak{A} in \overline{V}_{δ} is $\overline{a}>0$. Hence

$$\int_{\mathfrak{A}} f d\mathfrak{A} = \int_{\mathfrak{A}} f d\mathfrak{A} \ge \lambda \bar{\mathfrak{A}} > 0.$$

Hence f=0 at every point of continuity of $\mathfrak A$ in $\mathfrak B$. Let now D be a rectangular division of space. The reasoning of 721 shows that every cell which contains a point of $\mathfrak B$ also contains a point of continuity lying in $\mathfrak B$. Hence,

∄ა≅ნა;

which gives,

$$\overline{\mathfrak{Z}} \subseteq \overline{\mathfrak{B}}, \text{ or } \overline{\mathfrak{Z}} = \overline{\mathfrak{B}}.$$

Reduction of Multiple Integrals to Iterated Integrals

732. 1. Let $f(x_1 \cdots x_m)$ be limited in the limited field \mathfrak{A} . Let \mathfrak{F} , be the projection of \mathfrak{A} on the x-axis. Let \mathfrak{F} , be a plane section of \mathfrak{A} perpendicular to the x-axis. Then the (m-1) tuple upper and lower integrals

 $\int_{\mathbb{R}} f d\mathfrak{P}_{i}, \quad \int_{\mathbb{R}} f d\mathfrak{P}_{i}$ (1)

are one-valued limited functions of x_0 , defined over x_0 . For, let \mathfrak{A} lie in a cube of side C. Let $|f(x_1 \cdots x_m)| \leq F$. Then both integrals are numerically

 $< FC^{m-1}$

for any x, in g.

2 Each of the integrals 1) considered as functions of x defined over x have therefore upper and lower integrals in x viz

For brevity these may also be written

733 1 Let $f(x_1 \ x_2)$ be limited in the measurable field A Let x be the project on of A on the x axis Let x be the plane sections of A corresponding to the points of x. Then

$$\iint_{\mathbb{R}} d\mathbb{R} < \int_{\mathbb{R}} dz \int_{\mathbb{R}} dz \mathbb{R} < \int_{\mathbb{R}} dz \int_{\mathbb{R}} dz \mathbb{R} \le \iint_{\mathbb{R}} d\mathbb{R} \tag{1}$$

$$\int_{S} dx \int_{S} dx \int_{S} f dR < \int_{S} dx \int_{S} f dR < \int_{S} f dR$$
 (2)

Let us establish the relation 1) the demonstration of 2) is

Let X i e in an outer cube B whose projection on the x ax s is b an i w i ose plane sections perpendicular to this axis, we denote by Q

We introduce an auxiliary function

$$g(x_1 \quad x_m) = f(x_1 \quad x_m)$$
 at points of \mathfrak{A}

Let D be a cubical division of \Re_n of norm d. This divides \Re into cells which we denote by δ . It also divides the planes Ω into cells which we denote by δ and the segment δ into intervals which we denote by δ .

Let M M' denote the maxima and m, m the minima of $g(x_1 x_m)$ in the cells δ , δ Let G be the upper and lower

integrals of g in the field \mathfrak{B} . Let $|f(x_1 \cdots x_m)| \leq F$ in \mathfrak{A} . Then for each $\epsilon > 0$, there exists a d_0 such that

$$\underline{G} - \epsilon < \sum_{\mathfrak{B}} m\delta \le \sum_{\mathfrak{B}} M\delta < \overline{G} + \epsilon, \qquad d \le d_0. \tag{3}$$

Moreover, we note that for each x, of b,

$$\sum_{\Omega} m' \delta' \leq \int_{\Omega} g d\Omega \leq \sum_{\Omega} M' \delta'.$$

Or, since

$$m \le m'$$
 $M' \le M$

$$\sum_{\mathfrak{Q}} m \delta' \leq \int_{\mathfrak{Q}} g d\mathfrak{Q} \leq \sum_{\mathfrak{Q}} M \delta'.$$

Multiplying by δ'' , and summing over b, we have, since $\delta = \delta' \delta''$,

$$\sum_{\mathfrak{B}} m\delta \leq \sum_{\mathfrak{b}} \delta'' \int_{\mathfrak{D}} \leq \sum_{\mathfrak{D}} M\delta.$$

Making use of 3), this gives

$$\underline{G} - \epsilon < \sum_{\mathfrak{h}} \delta'' \underline{\int}_{\mathfrak{Q}} < \overline{G} + \epsilon,$$

for any $d \le d_0$. Thus, by 727,

$$\underline{G} - \epsilon < \underbrace{\int_{b} \int_{\Omega} \leq \overline{f}_{b} \int_{\Omega} \leq \overline{G} + \epsilon.}$$

Or, since ϵ is small at pleasure,

$$\underline{G} \leq \int_{b} \int_{\Omega} \leq \overline{\int}_{b} \int_{\Omega} \leq \overline{G}.$$
 (4)

But, by 725,

$$\underline{G} = \int_{S_1} f d\mathfrak{A}, \qquad \overline{G} = \int_{S_1} f d\mathfrak{A}.$$

Thus

$$\underline{\int}_{\Re} f d \mathbb{I} \leq \underline{\int}_{E} \underline{\int}_{\Omega} \leq \overline{\int}_{E} \underline{\int}_{\Omega} \leq \overline{\int}_{\Re} f d \mathbb{I}.$$
 (5)

Let $\overline{\mathfrak{F}}_{\mathfrak{P}}$ denote the upper content of the frontier points of \mathfrak{P}_{\bullet} . Then

$$\left| \int_{\mathcal{P}_{i}} f d\mathfrak{P} - \int_{\Omega} g d\Omega \right| \leq F \overline{\mathfrak{F}}_{\mathfrak{P}}. \tag{6}$$

Let

$$h(x_i) = \int_{\mathbb{R}^n} d\vec{p}_i$$
, for points of z_i ;
= 0, for other points of b.

Then, by 718, 1, 730, and 6),

$$\int_{\mathbb{R}} h(x_i) dx_i = \int_{\mathbb{R}} dx_i \int_{\Omega} g d\Omega$$

But, by 718, 3,

$$\int_{\mathbb{R}} h(x) dx = \int_{\mathbb{R}} h(x) dx = \int_{\mathbb{R}} dx \int_{\mathbb{R}} f d\mathfrak{P}_{\bullet}.$$

In the same way, we show

$$\int_{\mathbb{R}} dx \int_{\mathbb{Q}} g d\mathfrak{Q} = \int_{\mathbb{R}} dx \int_{\mathbb{R}} f d\mathfrak{P}_{\epsilon}$$

Thus 1) has been proved

2 In a similar manner we may demonstrate the following theorem

Let $f(x_1-x_n)$ be limited in the measurable field X. Let X, be the projection of X on the plane $x_i=0$. Let a_i be the rectilinear sections of X parallel to the x_i axis. Then

734 1 As corollaries of 733 we have

Let $f(x_1 x_n)$ be integrable in the measurable field $\mathfrak A$ Then

$$\begin{split} \int_{\mathbb{R}} f d\mathbb{R} &= \int_{\mathbb{R}} dx_i \underbrace{\int_{\mathbb{R}^i} f d\mathbb{R}_i}_{f} = \int_{\mathbb{R}} dx_i \underbrace{\int_{\mathbb{R}^i} f d\mathbb{R}_i}_{f} \\ &= \int_{\mathbb{R}^i} d\mathbb{R}_i \underbrace{\int_{\mathbb{R}^i} f dx_i}_{f} = \int_{\mathbb{R}^i} d\mathbb{R}_i \underbrace{\int_{\mathbb{R}^i} f dx_i}_{f} \end{split}$$

For, in this case,

 $\bar{\int}_{\mathbf{z}} = \bar{\int}_{\mathbf{z}}$

Hence the upper and lower integrals of $\int_{\mathbb{R}}$ and $\overline{\int}_{\mathbb{R}}$ are equal.

2. Let $f(x_1 \cdots x_m)$ be integrable in the measurable field \mathfrak{A} , as well as in each of its plane sections \mathfrak{P} . Then

$$\int_{\mathfrak{A}}fd\mathfrak{A}=\int_{\mathfrak{a}}d\mathfrak{a}\int_{\mathfrak{P}}fd\mathfrak{P}.$$

If f is integrable in each of the rectilinear sections a, we also have

$$\int_{\mathfrak{A}} f d\mathfrak{A} = \int_{\mathfrak{P}} d\mathfrak{P} \int_{\mathfrak{A}} f dx.$$

EXAMPLE

735. Let us find the volume V of the ellipsoid E,

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1.$$

By 708, 4, the surface forms a discrete aggregate; hence E has a volume.

By 702, 2,

$$V = \int_{\mathcal{E}} dx \, dy \, dz$$
$$= 8 \int_{\mathcal{E}}^{a} dx \int_{\mathcal{E}} dy \, dz,$$

where F is a quadrant of the ellipse

$$\frac{y^2}{b^2} + \frac{z^2}{c^2} = 1 - \frac{x^2}{a^2}, \quad 0 \le x \le a.$$

Hence

$$\begin{split} \int_{F} \! dy \, dz &= \int_{0}^{b} \! \sqrt{1 - \frac{x^{2}}{a^{2}}} \int_{0}^{e\sqrt{1 - \frac{x^{2}}{a^{2}} - \frac{y^{2}}{b^{2}}}} \\ &= c \int_{0}^{b} \! dy \sqrt{1 - \frac{x^{2}}{a^{2}} - \frac{y^{2}}{b^{2}}} \\ &= \frac{1}{4} b c \pi \left(1 - \frac{x^{2}}{a^{2}} \right). \end{split}$$

Thus

$$V = 2 \pi b c \int_0^a \left(1 - \frac{x^2}{a^2}\right) dx = \frac{4}{3} \pi a b c$$

736. Let $f(x_1 \cdots x_m)$ be limited and integrable in the measurable field \mathfrak{A} . Let $\sigma > 0$ be arbitrarily small. Let \mathfrak{x}_{σ} denote the points of \mathfrak{x}_{ι} for which

 $\int_{\mathfrak{M}} f d\mathfrak{P} - \int_{\mathfrak{M}} f d\mathfrak{P} \, \overline{\geq} \, \sigma.$

Then I, is ducrete If It is complete, the upper content of the points where this difference vanishes is F. A similar theorem holds for the differences

$$\int_{\mathbf{x}} f dx_i - \int_{\mathbf{x}} f dx_i$$

For, by 734, 1, $\int_{\mathbb{R}} f d\mathfrak{A} = \int_{\mathbb{R}} \int_{\mathbb{R}} = \int_{\mathbb{R}} \int_{\mathbb{R}} \cdot$

Hence

Ience
$$\int_{a} \int_{y_{1}} - \int_{a} \int_{y_{2}} = \int_{a} \left\{ \int_{y_{1}} - \int_{y_{2}} \right\} = 0.$$

The theorem follows now, by 731

737 1 Let A be a complete measurable field Let z, be its pro section on the x axis Let in be the points of x, for which the corresponding plane sections are measurable. Then h = 1.

A similar relation holds for the projection T.

For, let $f(x_i = x_m) = 1$, at frontier points & of X;

= 0, at other points of I.

Then, by 702,

$$0 = \int_{\mathcal{A}} f d\mathfrak{F} = \int_{\mathcal{A}} f d\mathfrak{F}$$

Since M is measurable, & is discrete, and hence measurable. Hence, by 784, 1,

 $0 = \int dx \int_{\mathcal{I}} f dx$

Hence, by 731, the points n at which

$$\int_{\mathbb{R}} f d\mathfrak{F} = 0$$

have the same upper content as r.

2 Let f(x, x,) be integrable in the measurable complete field A Let n, denote those points of z, for which the integrals over the corre sponding plane sections B. exist Let 9 denote the points of X for which the integrals over the corresponding rectilinear sections a exist Then

 $\int f dX = \int dx \int_{\mathbb{R}} f dP_{i} = \int_{\mathbb{R}} dP_{i} \int f dz,$ α Let us prove the first half of 1); the other half follows similarly.

By 734, 1

$$\int_{\mathfrak{A}} f d\mathfrak{A} = \int_{\mathfrak{r}_{\iota}} dx_{\iota} \int_{\mathfrak{P}_{\iota}} f d\mathfrak{P}_{\iota}$$

$$= \int_{\mathfrak{q}_{\iota}} dx_{\iota} \int_{\mathfrak{P}_{\iota}} f d\mathfrak{P}_{\iota}, \quad \text{by 726, 737,}$$

$$= \int_{\mathfrak{q}_{\iota}} dx_{\iota} \int_{\mathfrak{P}_{\iota}} f d\mathfrak{P}_{\iota},$$

$$\int_{\mathfrak{R}} = \int_{\mathfrak{R}}$$

since

at the points n.

Application to Inversion

738. 1. In 570 we saw that

$$\int_a^\beta dy \int_a^b f dx$$

admits inversion, if f(x, y) is limited in the rectangle $R = (ab\alpha\beta)$, and continuous except on a finite number of lines parallel to the x and y-axes. We can generalize this result as follows:

Let f(x, y) be limited in the rectangle $R = (aba\beta)$. Let the points of discontinuity Δ in R be discrete. Let the points of Δ on any line parallel to either axis form a discrete aggregate on that line. Then

$$\int_a^\beta dy \int_a^b f dx, \ \int_a^b dx \int_a^\beta f dy$$

exist and are equal.

For, by 719, 2, the double integral

$$\int_{R} f dR$$

exists. The theorem now follows from 734, 2.

2. If the points of discontinuity of f(xy) on any line parallel to the x or y-axes do not form a discrete aggregate, we may apply the following theorem:

Let f(xy) be limited in the rectangle $R = (aba\beta)$ If the points of discontinuity of f in R form a discrete aggregate see have

$$\int_{a}^{b} dy \int_{a}^{b} f dx = \int_{a}^{b} dy \int_{a}^{b} f dx = \int_{a}^{b} dx \int_{a}^{b} f dy = \int_{a}^{b} dx \int_{a}^{b} f dy$$

739 1 Let f(x y z) be limited in the rectangular parallelopipea R bounded by the planes x=a z=b y=a $y=\beta$ z=A z=BLet it be continuous in R except at the points of a discrete aggre gate A Let the points of A on any line or plane parallel to the axes be discrete with respect to that line or plane Then the triple iterated sntegral

$$\int_{1}^{a} dz \int_{1}^{a} dy \int_{1}^{a} f(xyz) dx$$

exists and admits unrestricted inversion

For.

$$\int_{\mathbb{R}} f(xyz)dR$$

exists by 719 2 Let P denote a plane section of R parallel to the x y plane Then the double integrals

$$\int_{z} f(zyz)dP \qquad A \leq z \leq B,$$

also exist by 719, 2 Hence by 734, 2,

$$\int_{R} f dR = \int_{A}^{B} dz \int_{P} f dP$$

But by 788, $\int f dP = \int^{p} dy \int^{p} f dx = \int^{q} dx \int^{q} f dy$

ar ar

Hence.

exist and are equal. In the same way we may treat the four other inversions

EXAMPLES

740. 1. Let
$$R = (0101)$$
. Let

$$f(x, y) = 0$$
, for irrational x, or y;

$$=\frac{1}{n}$$
 for $x=\frac{m}{n}$; m, n relative prime, and y rational.

Then

$$\int_{R} f(xy) dR$$

exists by 701, Ex. 1. Its value is easily seen to be 0, by 730.

We have now:

$$\underline{\int} f dx = 0, \ \underline{\int} f dy = 0.$$

Also

$$\int f dx = 0$$
, for irrational y, obviously;

= 0 for rational y, by 730.

Hence

$$\int_0^1 f dx = 0, \quad \text{for any } y;$$

and therefore

$$\int_0^1 dy \int_0^1 f dx = 0.$$

On the other hand,

$$\overline{\int_0^1} f dy = \frac{1}{n}, \quad \text{for } x = \frac{m}{n}.$$

Hence

$$\int_0^1 f dy$$

does not exist for rational x; i.e. for a point set which is not discrete.

However,

$$\int_0^1 f dy = 0$$

for any x. Hence, by 734, 1,

$$\int_{R} f dR = \int_{0}^{1} dx \int_{0}^{1} f dy;$$

which is obviously true.

This example illustrates the theorem of 736.

For, the points x at which

$$\overline{\int_0^1}fdy-\underline{\int_0^1}fdy \stackrel{\textstyle >}{ >} \frac{1}{n},$$

are the rational points p/q whose denominators $q \le n$.

Remark. Let R_{σ} denote the content of those points of R for which $f(xy) \gtrsim o$ Obviously

 $R_{\sigma}=0$. Hence $\lim_{\sigma\to 0}R_{\sigma}=0$.

It would therefore be wrong to infer that

Cont $\mathfrak{A}=0$,

because

Cont $\mathfrak{A}_{-}=0$.

for any $\sigma > 0$.

2 Let R be the rectangle (0101). Let us suppose the coordinates of its point x y expressed in the dyade express. CII W of editor now a part all aggregate R of P as follows. All this point x on ever a lines particle to the y at y, y, x, x, x, y, where 0 < x < 1 is any number having x has the superscention. Let x particular value of x embers of given in a representation. The properties are properties with the respect to x and y. If x are the properties x in the respect to x and y. If x is expression of x is not failt there is no point of R on the respect to x and y. If x is expression there are but x fine number of y on to R of R on R is an indicated on R of R of R is an indicated on R of R of R is an indicated of R of R of R of R of R is an indicated of R of R

Let us define now f(xy) as follows

Since the oscillation of f in any cell of R is 1 the double integral

Bowever

$$\int_0^1 f dx = \int_0^1 f dy = 1.$$

Hence both iterated integrals

exist and are equal. (Pringsheirs)

3. In the rectangle R = (6101) let us define another aggregate \Re as follows. As before the x of every point of \Re must have a finite representation. If the representation of a subtracte p d git with the points of the live p or belong to \Re whose ordinates are expressed by p or less d gits.

Thus on any given l as x = a are only a finite number of points of \mathbb{R} . On the contrary on any l (the segment of the time q = a be an infinity of points of \mathbb{R}) if the representation of a or b is not finite there is no point of \mathbb{R} on the lines x = a, or y = b is in $\mathbb{E} x$.

Let us define f(xy) as in Ex. 2

f(2y) = 0 for any point in B

= 1 for a point of R not in B.

Then as before the double integral

The integral

$$\int_0^1 f dx$$

does not exist for any y whose representation is finite, since

Hence

4. Let f(xy) be limited in the rectangle R = (0101). Let

$$\int_0^1 dy \int_0^1 f(xy) dx$$

The reader might be tempted to conclude that therefore

$$\int_a^\beta dy \int_a^b f dx, \qquad 0 \le \alpha < \beta \le 1, \qquad 0 \le \alpha < b \le 1,$$

exists. To show this is not always so, let us set with Du Bois Reymond,

Then
$$f(xy) = 1, \qquad \text{for rational } y;$$

$$= 2x, \qquad \text{for irrational } y.$$

$$\int_0^x f dx = x, \qquad \text{for rational } y.$$
Hence
$$\int_0^1 f dx = 1, \qquad \text{for any } y;$$
and therefore
$$\int_0^1 dy \int_0^1 f dx = 1.$$
On the other hand,
$$\int_0^1 dy \int_0^b f dx, \qquad 0 < b < 1,$$

$$\int_0^1 dy \int_0^b f dx = b^2, \qquad \int_0^1 dy \int_0^b f dx = b.$$

Transformation of the Variables

741. 1. Let

$$T; u_1 = \phi_1(t_1 \cdots t_m), \cdots u_m = \phi_m(t_1 \cdots t_m) (1)$$

be defined over an aggregate I. These equations may be regarded as defining a transformation T, which transfers the points $t = (t_1 \cdots t_m)$ of $\mathfrak A$ to the points $u = (u_1 \cdots u_m)$. The points t, u

may be regarded as lying in the same space, or in different spaces. What we have called the image of A defined by the equation 1) may now be regarded as the transformed aggregate of A, and may be denoted by M...

2 If the correspondence between the points of M and M_r is uniform, the equations 1) admit as solutions the one-valued in verse functions

$$t_1 = \theta_1(u_1 \quad u_m), \quad t_n = \theta_n(u_1 \quad u_m)$$
 (2)

The equations 2) regarded as a transformation, convert the points of M_T back to M. For this reason it is called the inverse transformation of T, and denoted by T^{-1}

3 The transformation

$$u_1 = t_1$$
 $u_m = t_m$

is a special case of 1) As it leaves every point of A essentially unaltered, it is called the identical transformation, and is denoted by 1

$$x_1 = \psi_1(u_1 \quad u_n), \quad x_n = \psi_n(u_1 \quad u_n)$$
 (3)

be another transformation defined over \mathfrak{A}_n , which we denote by U. The transformation resulting from the successive application of T and U is called their product and is denoted by TU. The transformation which is applied first is written first

The result of effecting T and then its inverse is to leave every point of M at rest. Hence TT-1 is the identical transformation, in symbols

$$TT^{-1} = 1$$

- 5 If \mathfrak{A}_T goes over into \mathfrak{A}_{T^0} on applying U to \mathfrak{A}_T , we may regard \mathfrak{A}_{T^0} as the image of \mathfrak{A} afforded by the equations 1), when we consider the ϕ 's as functions of the x's through the u's, as given by 3)
- 6 The functions ϕ being one valued, to any point in \mathfrak{A} corresponds one point in $\mathfrak{A}_{1, \mathfrak{A}_{1, \mathfrak{D}}}$. Suppose the correspondence between $\mathfrak{A}_{1, \mathfrak{A}_{1, \mathfrak{D}}}$ is uniform. Then the correspondence between $\mathfrak{A}_{1, \mathfrak{A}_{1, \mathfrak{D}}}$ is uniform.

For, suppose, for example, that to the point u of \mathfrak{A}_T correspond two points t, t' of \mathfrak{A} . If now x corresponds to u; to the point x will correspond at least the two points t, t'. The correspondence is thus not uniform between \mathfrak{A} , \mathfrak{A}_{TU} .

7. If the functions ϕ have first partial derivatives in \mathfrak{A} , we call

$$J_{T} = \frac{\partial(\phi_{1} \cdots \phi_{m})}{\partial(t_{1} \cdots t_{m})} = \begin{vmatrix} \frac{\partial\phi_{1}}{\partial t_{1}} \cdots \frac{\partial\phi_{m}}{\partial t_{1}} \\ \vdots & \ddots \\ \frac{\partial\phi_{1}}{\partial t_{m}} \cdots \frac{\partial\phi_{m}}{\partial t_{m}} \end{vmatrix}$$

the determinant of the transformation.

If the first partial derivatives of the ϕ 's are continuous in a region R, while the first partial derivatives of the ψ 's are continuous in a region containing R_T , we have, by direct multiplication of the determinants J_T , J_U , and using 430, 5),

$$J_{TU} = J_T \cdot J_U, \tag{4}$$

which we may state roughly thus:

The determinant of the product of two transformations is the product of their determinants.

742. 1. Let

$$T; u_1 = \phi_1(t_1 \cdots t_m), \cdots u_m = \phi_m(t_1 \cdots t_m) (1$$

have continuous first partial derivatives in the region R. Let the correspondence between R and R_T be uniform. Let the determinant of the transformation $J_T \neq 0$ in R. In this case we shall say the transformation T defined by the equations 1) is regular in R.

2. Let T be a regular transformation in R. Let t be a point of R, to which corresponds the point u. Let E be the image of $D_o(t)$. There exists an $\eta > 0$, such that $D_{\eta}(u)$ lies in E. Furthermore, if t runs over an inner aggregate $\mathfrak A$ of R, the η 's do not sink below some positive number η_0 .

For, suppose there exists no $\eta > 0$, such that $D_{\eta}(u)$ lies in E. Then there exists a sequence of points u_1, u_2, \cdots which $\doteq u$, and

7

which do not be in E. The inverse functions of 1) being one valued and continuous about u by 443 the image of the above points form a sequence t_1 t_2 which = t. Hence all the t_1 for $n \ge \operatorname{some} m$ he in $D_L(t)$, and thus u_{n-1} which = t. Hence all the t_1 for t_2 which = t. Hence all the t_2 which = t. Hence the t_1 wish the t_2 which = t. Hence the t_1 with the t_2 which t_3 is a contradiction. Thus extend the same that of the theorem. Turning to the second part suppose y = 0 as t runs over t. Then reasoning similar to that of t_3 t_2 leads at once to a contradiction

3 Let T be a regular transf rmation in the renon R Then R₁ is a reg on Let A be an inner agjregate of R To inner and frontier points of A correspond respectively inner and frontier points of B = A_T and conversely

This is a direct consequence of 2

4. If T is a regular transformation in the region R T is a regular transformation in R_T . The determinant of the inverse transformation is

$$J_{r-1} = \frac{1}{J_r}$$

This follows at once from 443 and 741 4)

5 Let T be a regular tran formation in the region R. Let A be an inner aggre, at of R and let D be its image. If either A or D is measurable the other is. If one is discrete, the other is

This follows from 4 and 708 3

743 1 Let T be a regular transformation

$$z_1 = \phi_1(t_1 \quad t_m) \quad x_m = \phi_m(t_1 \quad t_m) \quad (1)$$

in the region R Since $J_f \neq 0$ not all the derivatives

vanish at any point of R To fix the ideas, let

$$\frac{\partial \phi_{cc}}{\partial t} \neq 0$$
 (2)

at a point t, and hence, as it is continuous, in a certain domain $D_i(t)$ of t

We show now how T can be expressed as the product of two special regular transformations. The first transformation we define thus:

$$T_1;$$
 $u_1 = t_1, \cdots u_{m-1} = t_{m-1}, u_m = \phi_m(t_1 \cdots t_m).$ (3)

By virtue of 2) this system may be inverted, giving

$$t_1 = u_1, \cdots t_{m-1} = u_{m-1}, t_m = \theta(u_1 \cdots u_m).$$

Here θ is one-valued, and has continuous first partial derivatives in a certain domain $D_{\eta}(u)$. If $\delta' \leq \delta$ is taken sufficiently small, the image U of $D_{\delta'}(t)$ lies in $D_{\eta}(u)$.

We define the transformation T_2 over U by

$$T_2$$
; $x_1 = \phi_1(u_1 \cdots u_{m-1}\theta)$, $\cdots x_{m-1} = \phi_{m-1}(u_1 \cdots u_{m-1}\theta)$, $x_m = u_m$

where θ is the above one-valued function of the u's.

We see at once that

$$T = T_1 \cdot T_2$$

when t ranges over $D_{k'}(t)$.

Since

$$J_{T_1} = \frac{\partial \phi_m}{\partial t_m} \neq 0,$$

and

$$J_T = J_{T_1}J_{T_2} \neq 0,$$

it follows that $J_{T_1} \neq 0$ in U. Since the correspondence is uniform, and the functions ϕ , ψ have continuous first derivatives in the respective domains, the two transformations T_1 , T_2 are regular.

2. Let $\mathfrak A$ be a limited inner aggregate of the region R. We can effect a cubical division of the t space of norm d such that for the points of $\mathfrak A$ in each cell d_s , there exist two transformations $T_1^{(\kappa)}$, $T_2^{(\kappa)}$ of the type just considered, such that

$$T = T_1^{(\kappa)} T_2^{(\kappa)}. \tag{4}$$

For, we can take d so small that not all the first partial derivatives vanish in any cell. For if they did, reasoning similar to that of 264 shows that they must then vanish at some point of R, which would require J=0 at that point. Thus these cubes may be taken as the domains $D_{\delta}(t)$ in 1. By reasoning similar to that of 352, we show that the norms η of the domains $D_{\eta}(u)$ considered

in 1 do not sink below some positive number. The same reasoning applied to the norms & of the D, (t) above, shows that the norms & of the above Dr (t), are all greater than some positive number Thus if d is taken small enough, the relation 4) will hold in each cell containing points of A

744 Let.

$$T_1 = \phi_1(t_1 - t_m), \quad x_n = \phi_n(t_1 - t_\mu)$$

define a regular transformation of determinant J in the region RLet I be any unner measurable perfect aggregate of R, and let X be its image Let f(z, xa) be continuous in X Then

$$\int_{T} f(x_1 - x_n) dx_1 - dx_n = \int_{T} J | f dt_1 - dt_n$$
(1)

For m=1 the relation 1) is easily seen to be true, taking account of direction in I Let us therefore assume it is correct for m-1, and show it is so for m Let D be a cubical division of the t space, such that in each cell containing points of I the transformation T can be expressed as the product of two transformations

$$T_1, \quad u_1 = t_1, \quad u_m := t_{m-1}, \quad u_m = \phi_m(t_1 \quad t_m),$$

$$T_2, \quad z_1 = \phi_1(u_1 \quad u_{m-1}\theta), \quad z_{m-1} = \phi_{m-1}(u_1 \quad u_{m-1}\theta), \quad z_m = u_m,$$

of the type considered in 743

Let J. J. be their determinants Then

$$J = J_1 J_2$$

If the relation I) holds for each of the partial aggregates into which I falls after effecting D at obviously holds in I by 728 We may therefore assume, without loss of generality, that the same transformations T1 T2 may be employed throughout X

Let the image of X in the u space be II We have now

$$\begin{split} \int_{\mathbb{Z}} f dx_1 & dx_n = \int_{\mathbb{Q}} dx_n \int_{\mathbb{Q}_n} f dx_1 & dx_{n-1}, & \text{by 737, 2,} \\ & = \int_{\mathbb{Q}} \frac{1}{n} u_n \int_{\mathbb{Q}} \left[J_2 [f du_1 & du_{n-1}, & \text{by hypothesis,} \right] \end{split}$$

where b. T' are the transformed b. P. respectively.

Since X is measurable, U is so, by 742, 5. The same is true of T'. Hence, by 737, 2,

$$\int_{\mathfrak{X}} f dx_1 \cdots dx_m = \int_{\mathfrak{U}} |J_2| f du_1 \cdots du_m.$$

Applying the transformation T_1 to the integral on the right, similar considerations show that

$$\int_{\mathfrak{X}} f dx_1 \cdots dx_m = \int_{\mathfrak{X}} |J_1| |J_2| f dt_1 \cdots dt_m,$$

which is 1).

745. Let
$$x_1 = \phi_1(t_1 \cdots t_m), \cdots x_m = \phi_m(t_1 \cdots t_m)$$

define a regular transformation of determinant I, in the region R. To a rectangular division D of norm d of the t-space into cells d. corresponds a division Δ of norm δ of the x-space into cells δ_{κ} . Let \mathfrak{T} be any inner region of R, and \mathfrak{X} its image. The cells of Δ falling within X are unmixed, and their contents are

$$\delta_{\kappa} = |J| d_{\kappa} + \epsilon_{\kappa} d_{\kappa}, \qquad t \text{ in } d_{\kappa}$$
 (1)

where $|\epsilon_{\epsilon}| < \epsilon$ uniformly, on taking d sufficiently small.

For, $\mathfrak T$ being an inner region, to each inner rectangular cell d_{κ} of \mathfrak{T} , corresponds a measurable cell δ_x of \mathfrak{X} by 742, 5. cells δ_{ϵ} within \mathfrak{X} are unmixed, limited, perfect, and finite in number for any Δ .

Since the determinant J is continuous in \mathfrak{T} , we can take d_0 so small that in any d, in T,

$$|J| = |J_{\tau}| + \sigma_{\kappa}; \tag{2}$$

where τ_{κ} is any point d_{κ} , and

$$|\sigma_{\epsilon}| < \epsilon$$

for any division D of norm $\leq d_0$.

From 702, 2 and 744, 1), we have for divisions of norm $\leq d_0$,

Cont
$$\delta_{\kappa} = \int_{\delta_{\kappa}} dx_1 \cdots dx_m = \int_{d_{\kappa}} |J| dt_1 \cdots dt_m$$

$$= |J_{\tau_{\kappa}}| \int_{d_{\kappa}} dt_1 \cdots dt_m + \int_{d_{\kappa}} \sigma_{\kappa} dt_1 \cdots dt_m, \text{ by (2,}$$

$$= |J_{\tau_{\kappa}}| d_{\kappa} + \epsilon_{\kappa} d_{\kappa},$$
here
$$|\epsilon_{\kappa}| < \epsilon.$$

where

746 1 Let

$$T x_i = \phi_i(t_i t_m) x_m = \phi_m(t_i t_m)$$

define a regular transformation of determinant J in a region R Let I be any inner aggregate of R and let I be its image Let f(z, z.) be limited in I Then

$$\int_{\mathbb{Z}} f(x_1 - x_n) dX = \int_{\mathbb{Z}} f |J| d\mathcal{I}, \qquad (1)$$

$$\int_{\mathbb{Z}} f(x_1 - x_n) dX = \int_{\mathbb{Z}} f |J| d\mathcal{I} \qquad (2)$$

(3

(4

For let us effect a cubical division of the t space of norm d

To it corresponds a division of X into cells of norm & Let us cons der the integral on the left of 1) Using the cus tomary notation we have letting J denote the value of J at some

point in
$$d_0$$
 $\Sigma M\delta = \Sigma M(J(+\epsilon)d$ by 745 1)

But if
$$|f| < P$$
 in Ξ

$$|\Sigma \in Md| < \varepsilon F(C\overline{o}) \in \Sigma + \varepsilon) = \eta$$

Let us now consider the integral on the right of 1) In the cell d $\operatorname{Max} f \operatorname{Min}[J] \leq \operatorname{Max} f J | \leq \operatorname{Max} f \operatorname{Max}[J]$

if Max f is positive while the signs are reversed if it is negative Let us set M' = Max f(J)ın d

Then $M = M(|J| + \epsilon)$ | $\epsilon' | < \epsilon$ uniformly

since the oscillation of J in any d is uniformly < c Thus

$$\Sigma M'd = \Sigma M |J|d + \Sigma \epsilon' M d$$

where as in 4)
$$\Sigma M' d = \Sigma M |J| d + \Sigma \epsilon' M d \qquad (5)$$
$$|\Sigma \epsilon' M d| < \eta \qquad (6)$$

Thus 3) 5) give in connection with 4) 6)

which establishes the relation 1) Similarly we may prove 2)

2. From 1 a great variety of theorems may be deduced by a passage to the limit. We note here only the following:

Let

$$T; x_1 = \phi_1(t_1 \cdots t_m), \cdots x_m = \phi_m(t_1 \cdots t_m)$$

be continuous in the measurable aggregate \mathfrak{T} , containing all its frontier points \mathfrak{F} ; and regular in any inner measurable aggregate \mathfrak{U} . Let the determinant of T be limited in \mathfrak{T} . Let \mathfrak{X} , the image of \mathfrak{T} , be measurable also; and let its frontier be the image of \mathfrak{F} . Let $f(x_1 \cdots x_m)$ be limited in \mathfrak{X} . Then

$$\int_{\mathfrak{X}} f(x_1 \cdots x_m) d\mathfrak{X} = \int_{\mathfrak{T}} f|J| d\mathfrak{T},$$

provided either integral exists

For, let I be the image of U. Then, by 1,

$$\int_{\mathfrak{P}} = \int_{\mathfrak{u}}$$

Let now $11 \doteq \mathfrak{T}$, then $\mathfrak{I} \doteq \mathfrak{X}$.

Lectures on the THEORY OF ELLIPTIC FUNCTIONS

by Harris Hancock

Mothematicians, engineers and physicists will welcome this reissue of Harris Hancock's long-out-of-print exposition of the theory of elliptic functions. It is still one of the most helpful books in a field where the literature in English is highly limited. It is the only book in English offering so extensive a coverage of classical material, and is valued especially for its unusual fullness of treatment and its comprehensive discussion of both theory and applications.

In twenty-one chapters, Hancock carefully develops the theory of elliptic integrals beginning with formulas establishing the existence, formation, and treatment of all three types (rational, simply periodic, doubly periodic) and concluding with the most general description of these integrals in terms of the Riemann surface. The theories of Legendre, Abel, and Jocobi are developed first and then side by side the later corresponding functions of Weierstrass; and both are interconnected by means of the universal laws of Riemann, who provided the most general theory of analytic functions by introducing the surfaces on which algebraic integrals may be represented. The important contributory theorems of Hermite and Liouville are also fully developed.

Chapter headings: Preliminary Notions; Functions which have Algebraic Addition-Theorems; Existence of Periodic Functions; Doubly Periodic Functions; Construction of Doubly Periodic Functions; The Riemann Surface; The Problem of Inversion; Elliptic Integrals in General; The Moduli of Periodicity; The Jacobi Theta-Functions; The Functions sn u, cn u, dn u; Doubly Periodic Functions of the Second Sort; Elliptic Integrals of the Second Kind; Introduction to Weierstrass's Theory; The Weierstrassian Functions; The Addition Theorems; The Sigma-Functions; The Theta- and Sigma-Functions when Special Values are Given; Elliptic Integrals of the Third Kind; Methods of Representing Analytic Doubly Periodic Functions; The Determination of all Analytic Functions which have Algebraic Addition-Theorems.

40-page Table of Formulas. 76 figures. xxiii + 498pp. 5% x 8.

ELEMENTS OF THE THEORY OF FUNCTIONS

by Konrad Knopp

This is the first valume in the five valume set THE THEORY OF FUNC TIONS prepared by Konred Knopp, a mathematician of international renown It may be used separately or with other valumes in the series, or with any other text on theory of functions it is unusual in its field in being concers, clear, easy to fallow, yet complete and agrorium Demonstrations are full, and proofs ore given in detail

ELEMENTS OF THE THEORY OF FUNCTIONS provides the student with general background for more advanced study it is specially useful for the reader who is not a specialist in higher mathematics.

PARTIAL CONTENTS I COMPLEX NUMBERS AND THEIR GEOMETRIC REPRESENTATION Foundations Systems of complex numbers and the Gaussian plane of numbers. The Remons sphere of numbers if the Gaussian plane of numbers the Remons sphere of numbers if LINEAR FUNCTIONS AND CIRCULAR TRANSFORMATIONS Mapping by means of linear functions formed farms and porticular linear mappings III SETS AND SECUENCES POWER SERIES Point sets and sais of numbers sequences of numbers, infinite sense sets and sais of numbers sequences of numbers, infinite sense Power senses IV APACHYTIC FUNCTIONS AND CONFORMAL MAP PINOS Functions of a complex vonoble Analysic functions and can formal mapping V THE ELEMENTARY TRUNCTIONS Power and root formal mapping V THE ELEMENTARY TRUNCTIONS Power and root for the rotional functions The supposehol, Ingonometric, and hope boile functions. DOVER BOOKS ON SCIENCE BOOKS THAT EXPLAIN SCIENCE

CONCERNING THE NATURE OF THINGS, Sir William Bragg. Christmas lectures delivered at the Royal Society by Nobel laureate Why a spinning ball travels in a curved track, how uranium is transmitted to lead, etc. Partial contents atoms, gases, liquids, crystals, metals etc. Na scientific background needed, wonderful for intelligent high school student 32pp of photos, 57 figures xii \pm 232pp 5 $\frac{1}{2}$ x 8.

THE NATURE OF LIGHT AND COLOUR IN THE OPEN AIR, M. Minnaert Why is falling snow sometimes block? What causes mirages, the fata margano, multiple suns and moons in the sky, how are shodows formed? Prof. Minnaert of the University of Utrecht answers these and similar questions in optics, light, colaur, for non-specialists Perticularly valuable to nature, science students, painters, photographers Translated by H. M. Kremer Priest, K. Jay. 202 illustrations, including 42 photos. xvi + 362pp. 5% x 8

THE RESTLESS UNIVERSE, Max Barn. New enlarged version of this remarkably readable account by o Noble loureate. Moving from subatomic particles to universe, the author explains in very simple terms the lotest theories of wave mechanics. Partial contents air and its relatives, electrons & ions, including 7 animated sequences. 325pp 6 x 9. T412 Paperbound \$2.00

MATTER & LIGHT, THE NEW PHYSICS, L. de Broglie. Non technical papers by a Nobel laureate explain electromagnetic theory, relativity, matter, light and radiation, wave mechanics, quantum physics, philosophy af science Einstein, Planck, 8ohr, others explained so easily that no mathematical training is needed for all but 2 of the 21 chapters Unabridged Index 300pp 73S Paperbound \$1.7S

THE COMMON SENSE OF THE EXACT SCIENCES, W. K. Clifford. Introduction by James Newman, edited by Karl Pearson For 70 years this has been a guide to classical scientific and mathematical thought Explains with unusual clarity basic concepts, such as extension of meaning of symbols, characteristics of surface boundaries, properties of plane figures, vectors, Cartesian method of determining position, etc. Long preface by Bertrand Russell Bibliography of Clifford Corrected, 130 diagrams redrawn 249pp 53/4 x 8

THE EVOLUTION OF SCIENTIFIC THOUGHT FROM NEWTON TO EINSTEIN, A. d'Abra. Einstein s special and general thearnes of relativity, with their historical implications, are analyzed in non technical terms. Excellent occaunts at the contributions of Newton, Riemann, Weyl, Planck, Eddington, Moxwell, Larentz and others are treated in terms of space and time, equations of electromognetics, finiteness of the universe, methodology of science 21 diagrams 482pp 72 Paperbound \$2.00

WHAT 15 SCIENCE, Narman Campbell. This excellent introduction explains scientific method, role of mathematics, types of scientific laws Cantents 2 aspects of science, science & nature, laws of science, discovery of laws, explanation of laws, measurement & numerical laws, applications of science 192pp $5\frac{1}{2}$ x 8 S43 Paperbound \$1.25

THE RISE OF THE NEW PHYSICS, A. d'Abra. A hall million word exposition, formerly titled IHE DECLINE OF MECHANISM, for readers not versed in higher mathematics. The only thorough explonation, in everyday language, of the central core of madern mathematical physical theory, teoting both classical and modern theoretical physics, and presenting in terms olmost anyone can understand the equivalent of 5 years of study of mathematical physics. Scientifically imprecable caverage of mathematical physical theory from the Newtonian system up through the electronic theories of Dirac and Heisenberg and Fermi s statistics. Combines both history and exposition, provides a broad yet unified and detailed view, with constant comparison of classical and modern views on phenomena and theories. A must for anyone doing serious study in the physical sciences, JOURNAL OF THE FRANKLIN INSTITUTE. Extraordinary faculty. . to explain ideas and theories of theoretical physics in the language of daily life, 1515. Indexed 197 Illustrations ix + 982pp. 5½, x 8

TRICONOMETRY REFRESHER FOR TECHNICAL MEN, A. Albert Klaf. 913 detailed questions and onswers cover the most important aspects of plane and spherical Ingonometry. They will help you to brush up or to clear up difficulties in special areas.—The first portion at this book covers plane trigonometry, including ongles, quadronts, trigonometrical functions, graphical representation, interpolation, equations, logarithms, solution at triangle, use at the slide rule and similar topics-185 pages then discuss application of plane trigonometry to special problems in novigation, surveying, elosticity, orthitecture, and various fields of engineering. Small ongles, periodic lunctions, vectors, polar coordinates, De Maivre's theorem are fully examined—The third section of the book then discusses spherical trigonometry and the solution of spherical tringles, with their applications to terrestrial and astronomical problems. Methods of soving time with numerical colculations, simplification of principal functions at ongle, much proctical information moke this o most useful book—913 questions answered 1738 problems, trasvers to odd num bers 494 figures 24 pages at useful formulae, functions.

SYMBOLIC LOGIC

AN INTRODUCTION TO SYMBOLIC LOGIC, Susonne K Longer. Probably the clearest book ever written on symbolic logic for the philosopher, general scientist and laymon. It will be porticularly appreciated by those who have been rebuffed by other introductory works because of insufficient mothematical training. No special knowledge of mothematics is required. Starting with the simplest symbols and conventions, you are led to a remarkable grosp of the Boole Schroeder and Russell Whitehead systems clearly and guickly. PARTIAL CONTENTS Study of forms, Essentials of logical structure, Generalization, Classes The deductive system of classes, The algebra of logic, Abstraction of interpretation. Calculus of propositions, Assumptions of PRINCIPIA MATHEMATICA, Logistics, Logic of the syllogism, Proofs of theorems. One of the clearest and simplest introductions to a subject which is very much olive. The style is easy symbolism is introduced gradually, and the intelligent non mathematican should have no difficulty in following argument, MATHEMATICS GAZETTE. Revised, expanded second edition. Truth value tables. 368pp. 5% x 8. \$1.64. Paperfound \$1.75.

THE ELEMENTS OF MATHEMATICAL LOGIC, Paul Rosenbloom. FIRST PUBLICATION IN ANY LANGUAGE This book is intended for reoders who are motive mothematically, but have no previous training in symbolic logic. It does not limit itself to a single system, but covers the field as a whole. It is a development of lectures given at Lund University, Sweden in 1948 Portiol contents logic of classes, fundamental theorems, Boolean algebra, logic of propositions, logic of propositions, expressive languages, combinatory logics, development of mothematics within an object language, paradoxes, theorems of Post and Goedel, Church's theorem, and similar topics in 1949 5% x 8

THE LAWS OF THOUGHT, George Boole. This book founded symbolic logic some hundred years ogo. It is the 1st significant attempt to apply logic to all aspects of human endeavour Portical contents derivation of lows, signs & lows, interpretations, eliminations, conditions of a perfect method, analysis, Aristotellan logic, probability, and similar topics $xvi_{11} + 424pp$ 5½ x8 528 Paperbound \$2.00

ELEMENTARY MATHEMATICS FROM AN ADVANCED STANDPOINT, Fellx Klein.

This clossic text is an outgrowth of Klein's fomous integration and survey course of Gottingen Using one field af mothemotics to interpret, adjust, illuminate another, it covers basic topics In each oreo, illustrating its discussion with extensive analysis. It is especially volubble in considering areas of modern mathematics. Mokes the reader feel the inspiration of a great mathematician, inspiring teacher with deep insight into the foundations and interrelations, BULLETIN, AMERICAN MATHEMATICAL SOCIETY

- Vol. 1. ARITHMETIC, ALGEBRA, ANALYSIS. Introducing the concept of function immediately, it enlivers obstract discussion with graphical and geometrically perceptual methods. Partial contents indural numbers, extension of the nation of number, special properties, complex numbers. Real equations with real unknowns, complex quantities. Logarithmic, exponential functions, gonlometric functions, infinitesimal colculus. Transcendence of e and pi, theory of assembloges index 125 fgures ix + 247pp 53/4 x 8
- Vol. 2. GEOMETRY. A comprehensive view which accomponies the space perception inherent in geometry with analytic formulas which facilitate precise formulation. Partial contents Simplest geometric monifolds line segment, Grossmann determinant principles, clossification of configurations of space, derivative monifolds. Geometric transformations offine transformations, projective, have point transformations, tleary of the imaginary systematic discussion of geometry and its foundations. FREQUENCY CURVES AND CORRELATION, W. P. Elderton. 4th revised edition of a stondard work covering classical stabilistics. It is practical in approach, and one of the books most frequently referred to for clear presentation of bosic material. Portical contents. Frequency distributions. Method of mament. Pearson's frequency curves. Correlation. Theoretical distributions, spurious correlation. Correlation of characters not quantitatively measurable. Standard errors Test of acades of fit. The correlation ratio—contingency. Portiol carrelation. Corrections for moments, to any gamma functions, etc. Key to terms, symbols. Bibliography. 25 examples in text 40 useful tables. 16 figures. xi + 272pp. 5½ x 8½.

HYDRODYNAMICS, H. Dryden, F. Murnaghon, Harry Bateman. Published by the Notional Research Council in 1932 this enormous volume offers a complete coverage of classical hydrodynomics. Encyclopedic in quality Portial contents physics of fluids, motion, turbulent flow, compressible fluids, motion in 1, 2, 3 dimensions, viscous fluids rotating, laminar mation, resistance of motion through viscous fluid, eddy viscosity, hydroulic flow in channels of various shapes, discharge of gases, flow post obstacles, etc. Bibliography of over 2,900 items. Indexes 23 figures 634pp 5½, x B.

HYD.(DDYNAMICS, A STUDY OF LOGIC, FACT, AND SIMILITUDE, Gorrett Birkhoff. A stimulating application of pure mathematics to an applied problem. Emphasis is placed upon correlation of opplication of pure mothematics to an opplied problem temphosis is placed upon correlation of the ry and deduction with experiment. It examines carefully recently discovered paradoxes, theory of modelling and dimensional analysis, paradox & error in flows and free boundary theory. The author derives the classical theory of virtual mass from homogeneous spaces, and applies group theory to fluid mechanics. Index. Bibliography 20 figures, 3 plates. xiii + 186pp 5½ x 8 \$21 Clothbound \$3.50

HYDRODYNAMICS, Heroce Lomb. Internationally famous complete coverage of standard reference work on dynamics af liquids & gases background, for classical hydrodynamics Equations in Special Goses, Irrotational Motion of Liquid in 2 Dimensions, Motion of Solids through Liquid—Dynamical Theory, Vortex Motion, Tidal Waves, Surface Waves, Waves af Exponsion, Viscosity, Rotating Masses of Liquids. Excellently planned, arronged, clear, lucid presentation 6th enlarged, revised edition Index. Over 900 footnates, mostly bibliographical. 119 figures. xv + 738pp. 6½ x 9½.

INTRODUCTION TO RELAXATION METHODS, F. 5. Shaw. Fluid mechanics, design of electrical networks, forces in structural frameworks, stress distribution, buckling, etc. Solve linear simultaneous equations, linear ordinary differential equations, portial differential equations, Eigenvalue problems by reloxation methods. Detailed examples throughout Special tables for dealing with awkwordly-shaped boundaries. Indexes. 253 diagrams. 72 tables. 400pp. 5½ x 8

S244 Poperbound \$2.45

PARTIAL DIFFERENTIAL EQUATIONS OF MATHEMATICAL PHYSICS, A. G. Webster. A keystone work in the library of every mature physicist, engineer, researcher. Valuable sections on elasticity, compression theory, potential theory, theory of sound, heat conduction, wave propagation, vibration theory. Contents include deduction of differential equations, vibrations, normal functions, Fourier's series, Couchy's method, boundary problems, method of Riemann-Volterro. Spherical, cylindrical, ellipsoidal harmonics, applications, etc. 97 figures. vii + 440pp. 5% x 8.

THE THEORY OF GROUPS AND QUANTUM MECHANICS, H. Weyl. Discussions of Schroedinger's wave equation, de Broglie's waves of a particle, Jordon Hoelder theorem, Lie's continuous groups of transformations, Pouli exclusion principle, quantization of Maxwell-Trace field equations, etc. symmetry permutation group, algebra of symmetric transformation, etc. 2nd revised edition. Unitary geometry, quantum theory, groups, application of groups to quantum mechanics, symmetry permutation group, algebra of symmetric transformation, etc. 2nd revised edition. Bibliography, Index. xxii + 422pp. 53/4 x 8. S268 Clothbound \$4.50 S269 Paperbound \$1.95

PARTIAL DIFFERENTIAL EQUATIONS OF MATHEMATICAL PHYSICS, Harry Batemon. Solution of boundary value problems by means of definite analytical expressions, with wide range of representative problems, full reference to contemporary literature, and new material by the author. Partial contents: clossical equations, integral thearens of Green, Slokes, 2 dimensional problems, conformal representation, equations in 3 variables, polar coordinates, cylindrical, ellipsoidal, porabolaid, totaidal coordinates; non-linear equations, etc. Must be in the hands of everyance interested in boundary value problems, BULLETIN, AM MATH. SOC. Indexes. 450 bibliographic featners 175 examples. 29 illustrations. xxii + 552pp. 6 x 9. S15 Clothbound \$4.95

Thorough, systematic presentation of physical & mathematical aspects, limited mostly to real aptics." Stresses practical problem of maximum aberration permissible without affecting performance. All ordinary ray tracing methods, complete theory primary aberrations, enough higher aberration to design telescopes, low powered microscopes, photographic equipment. Covers fundamental equations, extra axial image points, transverse chromatic aberration, angular magnification, aplanatic optical systems, bending aflenses, oblique pencils, tolerances, secondary spectrum, spherical aberration (angular, longitudinal, transverse, zonal), thin lenses, dozens of similar topics. Index. Tables of functions of N. Over 150 diagrams. x + 518pp. 6½ x 9½.

SPACE-TIME-MATTER, Hermann Weyl. The standard treatise on the general theory of relativity," [Nature], written by a world tenowned scientists, pravides a deep clear discussion of the logical coherence of the general theory, with introduction to all the mathematical tools needed Maxwell, analytical geometry, non Euclidean geometry, tensor calculus, etc. Basis is classical space time, before obsorption of relativity. Partial contents Euclidean space, mathematical form, metrical continuum, relativity of time and space, general theory. 15 diagrams Bibliography New preface for this edition. xvili + 330pp 5½ x 8

RAYLEIGH'S PRINCIPLE AND ITS APPLICATION TO ENGINEERING, G. Temple & W. Bickley. Rayleigh's principle developed to provide upper and lower estimates of true value of fundamental period of a vibrating system, or condition of stability af elastic systems. Illustrative examples, rigorous proofs in special chapters. Partial contents Energy method of discussing vibrations, stability Perturbation theory, whirling af uniform shafts. Criteria of elastic stability. Application of energy method. Vibrating system. Proof, accuracy, successive approximations, application of Rayleigh's principle Synthetic theorems. Numerical, graphical methods. Equilibrium configurations, Ritz's method. 8ibliography. Index. 22 figures. Index. 22 figures. 156pp. 53%, x8. S307. Paperbound \$1.50.

PHYSICS, ENGINEERING

THEORY OF VIBRATIONS, N. W. McLachlan. Based on an exceptionally successful graduate course given at Brown University, this discusses linear systems having 1 degree of freedom, forced vibrations of simple linear systems, vibration af flexible strings transverse vibrations of bars and tubes, transverse vibration af circular plate, saund waves of finite amplitude, etc. Index 99 diagrams. 160pp. 5½ x 8

WAVE PROPAGATION IN PERIODIC STRUCTURES, L. Brillouin. A general method and application to different problems pure physics such as scattering of X rays of crystols, thermal vibration in recrystal lottices, electronic motion in metols and also problems of electrical engineering. Partial contents elastic waves in 1 dimensional lattices of point masses. Propagation of waves along 1 dimensional lattices. Energy flow 2 dimensional, 3 dimensional lattices. Mathieus equation Matrices and propagation of waves along an electric line. Continuous electric lines 131 illustrations. Bibliography Index xii + 253pp 53½ x 8

THE ELECTROMAGNETIC FIELD, Max Mason & Warren Weaver. Used constantly by graduote engineers Vector methods exclusively detailed treatment of electrostatics, expansion methods, with tables converting any quantity into obsolute electromagnetic, absolute electrostatic, practical units Discrete charges, ponderable bodies, Maxwell field equations, etc. Introduction Indexes 416pp 5% x 8

APPLIED HYDRO- AND AEROMECHANICS by L. Prondit and O. G. Tietjens. Presents, for the most port, methods which will be valuable to engineers. Cavers flow in pipes, boundary layers, airful theory, entry conditions, turbulent flow in pipes done theory, entry conditions, turbulent flow in pipes and the boundary layer, determining drog from measurements of pressure and velocity, etc. Unabridged, unaftered Index 226 figures 28 photographic plates illustrating flow pottems xvi + 311pp 5% x 8

FUNDAMENTALS OF HYDRO- AND AEROMECHANICS by L. Prondif and O. G. Tietjens. The well known standard work based upon Prandit's unique insights and including original contributions of Tietjens. Wherever possible, hydrodynamic theory is referred to practical considerations in hydroulics with the view of unifying theory and experience through fundamental lows. Presentation is exceedingly clear and, though primarily physical, proofs are rigorous and use vector onalysis to a considerable extent. Translated by L. Rosenhead. 186 figures. Index xvi. + 270pp. 51/4 x 8.

DYNAMICS OF A SYSTEM OF RIGID BODIES (Advanced Section), E. J. Routh. Revised 6th edition of a classic reference aid. Much of its material remains unique. Partial contents moving axes, relative motion, oscillations about equilibrium, motion. Motion of a body under no forces, only forces. Nature of motion given by linear equations and conditions of stability. Free, forced vibrations, constants af integration, calculus af finite differences, variations, procession and nutation, motion of the moon, motion of string, chain, membranes.

64 figures. 498pp. 5½ x 8.

5229 Paperbound. \$2.35

MECHANICS OF THE GYROSCOPE, THE DYNAMICS OF ROTATION, R. F. Deimel, Professor of Mechanical Engineering of Stevens Institute of Technology Elementary general treatment of dynamics of rotation, with special application of gyroscopic phenomena. No knowledge of vectors needed Velocity of a moving curve, acceleration to a point, general equations of motion, gyroscopic horizon, free gyro, motion of discs, the dammed gyro, 103 similar topics. Exercises 75 figures 203pp 5% x8.

GEOGRAPHICAL ESSAYS, William Mortis Davis. Modern geography & geomorphology rests an the fundamental work of this scientist. 26 famous essays presenting most important theories, field researches. Partial contents Geographical Cycle, Ploins of Marine and Subaerial Denudation, The Peneplain, Rivers and Valleys of Pennsylvania, Outline of Cape Cod, Sculpture of Mauntoins by Glociers, etc. "Long the leader and guide," ECONOMIC GEOGRAPHY. "Part of the very texture of geography... models of clear thought," GEOGRAPHIC REVIEW. Index. 130 figures. VI + 777pp. 5% x 8. S383 Poperbound \$2.95

INTERNAL CONSTITUTION OF THE EARTH, edited by Beno Gutenberg. Completely revised, brought up-to-date, reset. Prepared far the National Research Council this is a complete & therough coverage of such topics as earth origins, continent formation, nature & behavior of the earth's care, petrology of the crust, cooling farces in the core, seismic & earthquake materiol, gravity, elastic constants, stron characteristics and similar topics. "One is filled with admitration... a high standard... there is no reader who will not learn something from this book,"Landon, Edinburgh, Dublin, Philosophic Magazine. Largest bibliography in print: 1127 classified items. Indexes. Tables of constants. 43 diagrams. 439pp. 6% x 9%.

THE BIRTH AND DEVELOPMENT OF THE GEOLOGICAL SCIENCES, F. D. Adoms. Most thorough history of the earth sciences ever written. Geological thought from earliest times to the end of the 19th century, covering over 300 early thinkers & systems: fossils & their explonation, vulcanists vs. neptunists, figured stones & poleontology, generation of stones, dozens of similar topics. 91 illustrations, including medieval, renaissance woodcuts, etc. Index. 632 toolnales, mostly bibliographicol. 511pp. 51/3 x 8.

HYDROLOGY, edited by Ostor E. Meinzer. Prepared for the National Research Council. Detailed complete reference library on precipitation, evaporation, snow, snow surveying, glaciers, lakes, infiltration, sail maisture, ground water, runally, drought, physical changes produced by water, hydrology of limestone terrones, etc. Practical in application, especially valuable for engineers. 24 experts hove created the most up-to-date, most complete treatment of the subject, AM. ASSOC OF PETROLEUM GEOLOGISTS. Bibliography. Index. 165 illustrations. x1 + 712pp. 6% × 9% \$191 Poperbound \$2.95

DE RE METALLICA, Georgius Agricola. 400-year old classic tronsloted, annotated by former President Herbert Hoover. The first scientific study of mineralogy and mining, for over 200 years ofter its appearance in 1556, it was the standard treatise. 12 books, exhaustively annotated, discuss the history of mining, selection of sites, types of deposits, making pils, shofts, ventilating, pumps, crushing machinery, ossaying, smelting, refining metals, also solt, alum, nitre, glass making. Definitive edition, with all 289 16th century woodcuts of the ariginal. Bibliographical, historical introductions, bibliography, survey of ancient outhors. Indexes. A fascinating book for anyone interested in art, history of science, geology, etc. DELUXE EDITION, 289 illustrations. 672pp. 6½ x 10½. Eibrary cloth.

URANIUM PROSPECTING, H. L. Bornes. For immediate practical use, professional geologists considers uronium ares, geological occurrences, field conditions, all aspects of highly profitable occupation. Index. Bibliography. x + 117pp. $5\frac{1}{2}x 8$. T309 Paperbound \$1.00 7309 Poperbound \$1.00

BIOLOGICAL SCIENCES

THE BIOLOGY OF THE AMPHIBIA, G. K. Noble, Lote Curator of Herpetology of the Am. Mus. of Not. Hist. Probably the most used text on amphibia, unmotched in comprehensiveness, clotify, detail. 19 chapters plus 85-page supplement cover development, heredity; life history; edoptation; sex, integument, respiratory, circulatory, digestive, muscular, nervous systems; instinct, intelligence habits environment economic value, relationships, classification, etc. "Nathing comparable to it," C. H. Pope, Curator of Amphibia, Chicago Mus. of Not Hist. 1047 bibliographic references. 174 illustrations. 600pp. 5% x 8.

THE BIOLOGY OF THE LABORATORY MOUSE, edited by G. D. Snell. 1st prepared in 1941 by the staff of the Roscoe B. Jackson Memanal laboratory, this is still the standard treatise on the mouse, assembling on enarmous amount al material far which atherwise you would spend hours ef research. Embryology, reproduction, histology, spontaneous neoplosms, gene & chremosomes mutations, genetics of spontaneous tumor formation, genetics of spontaneous tumor formation, genetics of tumor formation, inbred, hybrid animals, parosites, infectious diseases, care & recarding Classified bibliography of 1122 items. 172 figures, including 128 photos, is + 497pp. 6½ x 9½. 5248 Clathbound \$6.00

BEHAVIOR AND SOCIAL LIFE OF THE HONEYBEE, Ronald Ribbands. Oustanding scientific study; a compendium of practically everything known about social life of the honeybee. Stresses behaviar of individual bees in field, hive. Extends van Frisch's experiments an communication among bees. Covers perception al temperature, gravity, distance, vibration, sound production; glands, structural differences wox production, temperature regulation, recognition communication; driffing, mating behavior, other highly interesting topics. Biolography of 690 references. Indexes. 127 diagrams, graphs, sections of bee anatomy, fine photographs. 352pp. 5410 Clothbound \$4.50

ELEMENTS OF MATHEMATICAL BIOLOGY, A. J. Lotko. A proneer classic, the first major attempt to apply modern mothematical techniques on a large scale to phenomena of biology, biochemistry, psychology, ecology, similar life sciences. Partial Contents Statistical meaning of irreversibility. Evolution as redistribution. Equations of kinetics of evolving systems; Chemical, interspecies equilibrium; parameters al state; Energy transformers of nature, etc. Can be read with profit even by these having no advanced math; unsurpossed as study-reference. Formerly titled ELEMENTS OF PHYSICAL BIOLOGY. 72 figures. xxx + 460pp. 5% x 8.
